COMPUTATIONS IN RELATIVE ALGEBRAIC K-GROUPS

WERNER BLEY AND STEPHEN M. J. WILSON

Abstract. Let \( G \) be finite group and \( K \) a number field or a \( p \)-adic field with ring of integers \( \mathcal{O}_K \). In the first part of the manuscript we present an algorithm that computes the relative algebraic \( K \)-group \( K_0(\mathcal{O}_K[G], K) \) as an abstract abelian group. We solve the discrete logarithm problem, both in \( K_0(\mathcal{O}_K[G], K) \) and the locally free class group \( \text{cl}(\mathcal{O}_K[G]) \). All algorithms have been implemented in MAGMA for the case \( K = \mathbb{Q} \).

In the second part of the manuscript we prove formulae for the torsion subgroup of \( K_0(\mathbb{Z}[G], \mathbb{Q}) \) for large classes of dihedral and quaternion groups.

1. Introduction

Let \( G \) denote a finite group. The study of the locally free class group \( \text{cl}(\mathbb{Z}[G]) \) has been to a very large extent motivated by questions and conjectures arising in the field of Galois module theory. Among the large amount of existing work we mention Fröhlich’s conjecture (proved by Martin Taylor [19]) on the Galois module structure of rings of integers in tame Galois extensions of number fields and the \( \Omega \)-conjectures of Chinburg [9], extending and generalizing Fröhlich’s conjecture.

The locally free class group \( \text{cl}(\mathbb{Z}[G]) \) is the subject of the following exact sequence which is a truncation of the \( K \)-theory exact sequence of the functor \( \otimes_{\mathbb{Z}} \mathbb{R} \) from projective \( \mathbb{Z}[G] \)-modules to \( \mathbb{R}[G] \)-modules,

\[
K_1(\mathbb{Z}[G]) \longrightarrow K_1(\mathbb{R}[G]) \longrightarrow K_0(\mathbb{Z}[G], \mathbb{R}) \xrightarrow{\partial_0} \text{cl}(\mathbb{Z}[G]) \longrightarrow 0.
\]

Here, \( K_0(\mathbb{Z}[G], \mathbb{R}) \) is the relative \( K_0 \) of the functor. (See Section 2.1 for a brief definition of this and similar relative groups or see [17, p. 215]. For a more general view see [1, VIII §5]). The interest in \( K_0(\mathbb{Z}[G], \mathbb{R}) \) stems mainly from arithmetic geometry, where in recent years the study of the values of motivic \( L \)-functions at the integers has led to some remarkable conjectures formulated in terms of elements in \( K_0(\mathbb{Z}[G], \mathbb{R}) \). Among this large body of work we mention the Equivariant Tamagawa Number Conjectures of Burns and Flach. In special cases (namely for Tate motives) these conjectures refine and generalize the conjectures of Fröhlich and Chinburg mentioned above, cf. [7], [4], [6]. Stark-type conjectures imply the validity of the Equivariant Tamagawa Number conjectures modulo the rational subgroup \( K_0(\mathbb{Z}[G], \mathbb{Q}) \) of \( K_0(\mathbb{Z}[G], \mathbb{R}) \). It is therefore of particular interest to study \( K_0(\mathbb{Z}[G], \mathbb{Q}) \).

Let \( K \) be a number field and write \( \mathcal{O}_K \) for its ring of algebraic integers. In [2], Bley and Boltje described an algorithm for the explicit computation of the locally free class group \( \text{cl}(\mathcal{O}_K[G]) \). This algorithm was implemented in MAGMA for the case \( K = \mathbb{Q} \). Extending the methods of loc.cit., we derive an explicit description of the relative group \( K_0(\mathcal{O}_K[G], K) \) which is suitable for numerical

Date: May 14, 2007.
computations. Based on this description we develop algorithms for the computation of $K_0(\mathcal{O}_K[G], K)$, as well as for the solution of the discrete logarithm problem in $K_0(\mathcal{O}_K[G], K)$. Using (1) together with an explicit description of $\partial^0$ this also solves the discrete logarithm problem in $\text{cl}(\mathcal{O}_K[G])$. Finally, we describe how to compute the natural induction, restriction and quotient maps with respect to our explicit description of the relative group.

All algorithms have been implemented in MAGMA for $K = \mathbb{Q}$. We conclude the first part of the manuscript with some remarks on this implementation. The source code and tables of numerical results are available from http://www.mathematik.uni-kassel.de/~bley/pub.html.

The second part of this manuscript is motivated by the following two observations.

(a) There were few theoretical results for checking the correctness of our implementation.

(b) Our numerical results clearly show that for certain types of groups, namely dihedral and generalized quaternion groups, one could expect nice and systematic results.

We recall that the relative group that we target has a prime-by-prime decomposition

$$K_0(\mathcal{O}_K[G], K) \cong \prod_p K_0(\mathcal{O}_{K_p}[G], K_p),$$

where the coproduct extends over all non-zero prime ideals $p$ of $\mathcal{O}_K$. Each of the groups $K_0(\mathcal{O}_{K_p}[G], K_p)$ is finitely generated and modulo torsion is simply described. (It is naturally isomorphic to the character group of $G$ over $K_p$.) The more difficult and interesting part is its torsion subgroup,

$$DT(\mathcal{O}_{K_p}[G]) := K_0(\mathcal{O}_{K_p}[G], K_p)_{\text{tors}}.$$

By using sequences derived from cartesian squares and the special opportunities afforded by twisted group rings (extending the methods of [21]) we prove the following results.

**Theorem 1.1.** Let $G$ be a quaternion or dihedral group of order $2^n m$ with $(2, m) = 1$.

(a) Let $p$ be prime such that $p \mid m$ and $p^2 \nmid m$. Then

$$DT(\mathbb{Z}_p[G]) \cong \mathbb{F}_p^\times \times \prod_{1<d|2^{n-1}m/p} \left(\mathbb{F}_p^\times /\{\pm 1\} \right)^{s_d/r_d},$$

where $s_d$ is the order of the group $U_d := (\mathbb{Z}/d\mathbb{Z})^\times /\{\pm 1\}$ and $r_d$ is the order of $p$ in $U_d$.

(b) Suppose that $n = 2$ or $3$. Then

$$DT(\mathbb{Z}_2[G]) \cong C_2 \times C_2^{(n-2)m+1} \times \prod_{1<d|m} \left(\mathbb{F}_2^\times /\{\pm 1\} \right)^{(n-1)s_d/r_d},$$

where $s_d$ is the order of the group $U_d := (\mathbb{Z}/d\mathbb{Z})^\times /\{\pm 1\}$ and $r_d$ is the order of $2$ in $U_d$.

Our methods of proof apply to a much larger class of groups and we refer the reader to Theorem 8.15 for a general result on metacyclic groups. As a further example we state
Theorem 1.2. Let $A_4$ be the alternating group of order 12. Then $DT(\mathbb{Z}_5[A_4])$ and $DT(\mathbb{Z}_2[A_4])$ both have order 2.

2. Relative $K$-groups and their torsion

Much of this theory goes through very generally (see [1, Chapters VII to IX] and e.g. [22]) but we restrict ourselves to the cases in point. We suppose that $K$ is a finite extension field of $\mathbb{Q}$ (the global case) or $\mathbb{Q}_p$ (the local case). (After subsection 2.1 we assume that $K$ itself is global). We put $O_K$ for the ring of integers of $K$. Indeed, if $L$ is a sum, $\oplus_i O_{K_i}$, of such fields we put $O_L$ for its maximal order, $\oplus_i O_{K_i}$, and we denote by $I(L)$ the group of fractional ideals of $O_L$ (so $I(L) \cong \oplus_i I(K_i)$).

We take $A$ to be an $O_K$-order in a semi-simple $K$-algebra $E$ and we choose a maximal order $M$ in $A$ containing $A$. Since the index $[M : A]$ is finite, there is a full (two-sided) ideal of $M$ contained in $A$ (e.g. $[M : A]M$) and we choose such an ideal $f$, our conductor. We take $C$ to be the centre, $Z(A)$, of $A$ and we put $g := O_C \cap f$. We write $\mathcal{P}(R)$ for the category of finitely generated projective $R$-modules.

Let $E/K$ be a field extension. We consider the category $\Phi(\mathcal{P}(A), \otimes_{O_K} E)$ whose objects are triples $(P, \varphi, Q)$, where $P, Q \in \mathcal{P}(A)$ and $\varphi : P \otimes_{O_K} E \to Q \otimes_{O_K} E$ is an isomorphism of $A \otimes_K E$-modules. A morphism $(P, \varphi, Q) \to (P_1, \varphi_1, Q_1)$ is a pair of morphisms $u : P \to P_1$, $v : Q \to Q_1$ of $A$-modules such that $\varphi_1 \circ (u \otimes \text{id}_E) = (v \otimes \text{id}_E) \circ \varphi$. Clearly, this morphism is an isomorphism if and only if $u$ and $v$ are isomorphisms. We denote the isomorphism class of $(P, \varphi, Q)$ by $((P, \varphi, Q))$. We say that a sequence $0 \to (P_1, \varphi_1, Q_1) \to (P, \varphi, Q) \to (P_2, \varphi_2, Q_2) \to 0$ in this category is a short exact sequence if the component sequences $0 \to P_1 \to P \to P_2 \to 0$ and $0 \to Q_1 \to Q \to Q_2 \to 0$ are short exact sequences.

The group $K_0(A, \otimes_{O_K} E)$, the relative $K_0$ of $A$ with respect to the functor $\otimes_{O_K} K$, is the abelian group generated by isomorphism classes of such triples with relations $((P, \varphi, Q)) - ((P_1, \varphi_1, Q_1)) = (P, \varphi_1, Q_2)$ for each short exact sequence as above and $((P, \varphi, Q)) - ((P, \psi, R)) - ((Q, \varphi, R))$ for each $P, Q, R \in \mathcal{P}(A)$ and isomorphisms $\varphi : Q \otimes_{O_K} E \to R \otimes_{O_K} E$ and $\psi : P \otimes_{O_K} E \to Q \otimes_{O_K} E$. We write $[P, \varphi, Q]$ for the image of $(P, \varphi, Q)$ in $K_0(A, \otimes_{O_K} E)$. If the ground field $K$ is understood (as in the case where $A = O_K[G]$ for some finite group $G$) one often writes $K_0(A, E)$ for $K_0(A, \otimes_{O_K} E)$.

In fact, for any such $E$, $K_0(A, K)$ may be identified with a subgroup of $K_0(A, E)$ and is, indeed, the most interesting part. So we shall restrict our attention to $K_0(A, K)$. It is worth noting that, as can be readily deduced from the work below, if $A$ is commutative then the group, $I(A)$, of invertible fractional ideals of $A$ is isomorphic to $K_0(A, K)$ (by $a \mapsto [a, 1, A]$). Thus $K_0(A, K)$ can be viewed as a (commutative) generalization of $I(A)$ for non-commutative $A$.

We put $DT(A)$ for the torsion subgroup of $K_0(A, K)$. Note that up to a natural isomorphism $K_0(A, K)$ depends only on $A$, since the functors, $\otimes_2 \mathbb{Q}$, $\otimes_{O_K} K$ and $A \otimes A$ from $\mathcal{P}(A)$ to $\mathcal{P}(A)$ are isomorphic. Indeed, $K_0(A, K)$ has an alternative description as $K_0(H^1(A))$ (also written $K_0(T(A))$, the Grothendieck group (with respect to exact sequences) of $H^1(A)$, the category of $\mathbb{Z}$-torsion $A$-modules of finite
projective dimension (see [1, p. 432]). It then follows from the Chinese Remainder Theorem that, for $K$ global, we have the following decompositions induced by the localisation functors:

$$(2) \quad K_0(A, K) \simeq \prod_p K_0(A_p, K_p), \quad DT(A) \simeq \prod_p DT(A_p).$$

Here the products run over all the non-zero prime ideals $p$ of $\mathcal{O}_K$.

**Remark 2.1.** We choose our notation "$DT(A)$" because (see Theorem 2.4(iii)) for a group ring $A$, at least, $DT(A)$ bears a similar relation to $K_0(A, K) = K_0T(A)$ as the "kernel" subgroup, $D(A)$ does to $K_0(A)$. Indeed, $\partial^0$ maps $DT(A)$ onto $D(A)$.

If $\rho : R \to S$ is a ring homomorphism we write $k_i(\rho) : K_i(R) \to K_i(S)$ for the homomorphisms induced by $S \otimes_R$. We recall ([1, VII 5.3 or IX 6.3]) that our relative group, as this name suggests, fits into the exact sequence of the functor $A \otimes_A : \mathcal{P}(A) \to \mathcal{P}(A)$:

$$(3) \quad K_1(A) \xrightarrow{k_1(\lambda)} K_1(A) \xrightarrow{\delta_A} K_0(A, K) \xrightarrow{\partial^0} K_0(A) \xrightarrow{k_0(\lambda)} K_0(A)$$

Here $\delta_A([A^n, \varphi]) = [A^n, \varphi, A^n]$, $\partial^0[P, \varphi, Q] = [P] - [Q]$ and $\lambda : A \to A$ is the inclusion map.

We make considerable use of the reduced norm $nr = nr_A : A^\times \to C^\times$ and its extension and restriction to $K_1(A)$ and $K_1(\mathfrak{a})$, which we shall also denote $nr$. In view of (2) our work on the relative group will be almost exclusively with local orders, even if we keep a global order in mind. We now group together a number of the local results to which we shall need to refer. Recall that $SK_1(A)$ is the kernel of the reduced norm on $K_1(A)$.

**Theorem 2.2.** In the local case:

(i) $nr : K_1(A) \to C^\times$ is an isomorphism and $nr(A^\times) = C^\times$.

(ii) $nr_A \circ \delta_A^{-1}$ induces an isomorphism $\pi_A : \delta_A(K_1(A)) \to C^\times/nr(K_1(A))$. This is natural with respect to extension of order: if $\mathfrak{b}$ is an order containing $A$ then we have a commutative square.

$\begin{array}{ccc} 
\delta_A(K_1(A)) & \xrightarrow{\pi_A} & C^\times/nr(K_1(A)) \\
\downarrow & & \downarrow \\
\delta_B(K_1(A)) & \xrightarrow{\pi_B} & C^\times/nr(K_1(\mathfrak{b})) 
\end{array}$

(iii) The map $A^\times \to K_1(A)$ is surjective and so $nr(A^\times) = nr(K_1(A))$.

(iv) If $A$ is hereditary then $nr(A^\times) = \mathcal{O}_C^\times$.

(v) If $A$ is commutative then $SK_1(A) = \{0\}$ and $nr : K_1(A) \to A^\times$ is an isomorphism.

(vi) $K_0(A)$ is torsion free.

**Proof.** (i) We have $nr(A^\times) = nr(K_1(A)) = C^\times$ (see e.g. [8, Theorem 7.48] or [20, X, Prop. 6]) and, by Wang’s theorem [18], $SK_1(A) = \{0\}$ (but this case is due to Nakayama and Matsushima [15]).

(ii) $\pi_A$ is the composition of the two isomorphisms

$$(\delta_A^{-1}) \quad K_1(A)/\text{img}(K_1(A)) \xrightarrow{(nr_A)} C^\times/nr(K_1(A)).$$

The naturality follows from the fact that $[B \otimes_A] \circ \delta_A = \delta_B$.

(iii), (v) & (vi) See [1, IX 1.4] ($A$ is semilocal).

(iv) See e.g. [22, Theorem 2].
Part (ii) is a little unsatisfactory as it involves the rather \textit{ad hoc} $\delta_A(K_1(A))$ (though this may be nicely described as the subgroup of triples involving only free modules). The situation for group rings is neater.

\begin{theorem}
In the local case, if $\mathcal{A}$ is a group ring or a maximal order then
\begin{enumerate}
  \item In (3), $k_0(\lambda)$ is an isomorphism and so $\delta_A(K_1(\mathcal{A})) = K_0(\mathcal{A}, K)$.
  \item $\pi_A$ is an isomorphism $\pi_A : K_0(\mathcal{A}, K) \to C^\times/\nr(K_1(\mathcal{A}))$.
  \item If $\mathcal{A}$ is a maximal order then $\pi_A : K_0(\mathcal{A}, K) \to C^\times/\mathcal{O}_C^\times \cong I(C)$.
\end{enumerate}
\end{theorem}

\textit{Proof.} (i) See [1, X 1.3 & 1.4] — $\square$.

For (ii) see Theorem 2.2(ii) and for (iii) see Theorem 2.2(iv). $\square$

It follows from Theorem 2.3(i) (after a certain amount of diagram chasing) that, in the global case, if $\mathcal{A}$ is a group ring or a maximal order then the cokernel of $\delta_A$ consists of the locally trivial elements of $K_0(\mathcal{A})$, that is $\text{cl}(\mathcal{A})$, the locally free class group. So we have an exact sequence

$$K_1(\mathcal{A}) \to K_1(\mathcal{A}) \to K_0(\mathcal{A}, K) \to \text{cl}(\mathcal{A}) \to 0$$

(see [8, Th. (32.1)] or [22, (7)]).

We can now give a formula for $DT(\mathcal{A})$ in terms of reduced norms.

\begin{theorem}
In the local case:
\begin{enumerate}
  \item $\pi_A$ gives an isomorphism from $DT(\mathcal{A})$ to $\mathcal{O}_C^\times/\nr(\mathcal{A}^\times)$, and this group is finite.
  \item If $\mathcal{A}$ is hereditary then $DT(\mathcal{A}) = \{0\}$.
  \item The map on relative groups induced by ring extension $(\mathcal{M} \otimes \mathcal{A})$ from $\mathcal{A}$ to a maximal order gives an exact sequence
  \begin{equation}
  0 \to DT(\mathcal{A}) \to \delta_A(K_1(\mathcal{A})) \to K_0(\mathcal{M}, K) \to 0.
  \end{equation}
  \item Non-canonically, $\delta_A(K_1(\mathcal{A})) \cong I(C) \times DT(\mathcal{A})$.
\end{enumerate}
\end{theorem}

\textit{Proof.} Note first that by (3) and Theorem 2.2(vi), $DT(\mathcal{A}) \subseteq \delta_A(K_1(\mathcal{A}))$ so that $DT(\mathcal{A}) = \delta_A(K_1(\mathcal{A}))_{\text{tors}}$. By Theorem 2.2(ii) and Corollary 2.3, we have a commutative diagram with exact rows and vertical isomorphisms (the one on the left being forced by the other two):

\begin{equation}
\begin{array}{ccc}
0 & \to & \ker([\mathcal{M}\otimes]) \\
\downarrow \pi_A & & \downarrow \pi_A \\
\ker([\mathcal{M}\otimes]) & \to & \delta_A(K_1(\mathcal{A})) \\
\downarrow \pi_M & & \downarrow \pi_M \\
0 & \to & \mathcal{O}_C^\times/\nr(\mathcal{A}^\times) \\
\end{array}
\end{equation}

We find (recall that the conductor $\mathcal{f}$ was chosen above) that

$$\mathcal{O}_C^\times/\nr(\mathcal{A}^\times) = \mathcal{O}_C^\times/\nr(\mathcal{A}^\times) \leq |\mathcal{M}^\times/\mathcal{A}^\times| \leq |\mathcal{M}^\times/(\mathcal{Z}_p + \mathcal{f})^\times| \leq |(\mathcal{M}/\mathcal{f})^\times| < |\mathcal{M}/|\mathcal{f}|.$$  

So $\ker([\mathcal{M}\otimes] \cong \mathcal{O}_C^\times/\nr(\mathcal{A}^\times))$ is finite. Moreover $K_0(\mathcal{M}, K) \cong I(C)$ is torsion free. Thus

$$DT(\mathcal{A}) = \ker([\mathcal{M}\otimes] \cong \mathcal{O}_C^\times/\nr(\mathcal{A}^\times))$$

and we have parts (i) and (iii). Moreover, since $I(C)$ is torsion free, (5) splits and part (iv) follows.

Also, part (ii) follows from part (i) and Theorem 2.2(iv). $\square$
In the global case $A_p$ is a maximal order for all but finitely many maximal ideals $p$ of $\mathcal{O}_K$ so we have from (2):

**Corollary 2.5.** In the global case, also, $DT(A)$ is finite.

We now give a description of $DT(A)$ in terms of calculable finite groups. Recall we have chosen a conductor $\mathfrak{f}$ for $A$ relative to $M$ and that $g = \mathfrak{f} \cap C$.

**Theorem 2.6.** (i) The reduced norm on $A$ induces a homomorphism

$$\mu : K_1(A/\mathfrak{f}) \longrightarrow (\mathcal{O}_C/g)^\times.$$ 

(ii) We have a canonical isomorphism $DT(A) \sim \text{cok}(\mu)$. In the local case it is induced by $\Pi_A$.

**Proof.** We consider the local case first.

(i) Put $U_1(A) := \{a \in A^\times \mid a \equiv 1 \mod \mathfrak{f}\}$.

Note that $U_1(A) = U_1(M)$. By [2, Cor. 2.4], $\text{nr}(U_1(M)) = U_1(\mathcal{O}_C)$. Whence, also, $\text{nr}(U_1(M)) = U_1(\mathcal{O}_C)$, where $M = \text{Mat}_n(A)$. Thus the reduced norm induces a map

$$\tilde{\mu} : GL(A/\mathfrak{f}) \longrightarrow (\mathcal{O}_C/g)^\times.$$ 

and hence the map $\mu$ of (i).

(ii) We can now construct a diagram with exact rows:

$$
\begin{array}{cccccc}
0 & \rightarrow & U_1(A) & \rightarrow & A^\times & \rightarrow & (A/\mathfrak{f})^\times & \rightarrow & 0 \\
& & \downarrow \text{nr} & & \downarrow \text{nr} & & \mu' & & \\
0 & \rightarrow & U_1(\mathcal{O}_C) & \rightarrow & \mathcal{O}_C^\times & \rightarrow & (\mathcal{O}_C/g)^\times & \rightarrow & 0 \\
\end{array}
$$

where $\mu'$ factors via $\mu$ and has the same image since the map from $(A/\mathfrak{f})^\times$ to $K_1(A/\mathfrak{f})$ is surjective (the ring is semilocal). Now, since the left hand vertical map is surjective the cokernels of the other two are isomorphic. By Theorem 2.4(i) the cokernel of the central arrow is canonically isomorphic to $DT(A)$.

In the global case, for each maximal ideal $p$ of $\mathcal{O}_K$ the work above gives us maps

$$\mu_p : K_1(A_p/\mathfrak{f}_p) \rightarrow ((\mathcal{O}_C)_p/g_p)^\times$$

and then isomorphisms induced by the Chinese Remainder Theorem give us our homomorphism $\mu$ as the composite

$$\mu : K_1(A/\mathfrak{f}) \sim \bigoplus_p K_1(A_p/\mathfrak{f}_p) \bigoplus_p ((\mathcal{O}_C)_p/g_p)^\times \sim (\mathcal{O}_C/g)^\times.$$ 

Thus we obtain the composite isomorphism:

$$DT(A) \sim \bigoplus_p DT(A_p) \sim \bigoplus_p \text{cok}(\mu_p) \sim \text{cok}(\mu).$$

\[\square\]

### 2.2. Local decomposition and uniformising parameters.

In this section, continuing with the assignments and notation established above, we assume the global case (so $K$ is a finite extension of $\mathbb{Q}$) and set up notation to deal with the decomposition of $A$ and the further decomposition of $A_p$ for maximal ideals $p$ of $\mathcal{O}_K$. We finish by describing how, in the case where $A$ is a group ring, we set up an explicit isomorphism between $K_0(A_p, K_p)$ and $I(C_p) \times \text{cok}(\mu_p)$. 

The primitive idempotents of $C = Z(A)$ will be denoted by $e_1, \ldots, e_r$. For $i = 1, \ldots, r$, we set $A_i := \alpha e_i$. Then

$$A = A_1 \oplus \cdots \oplus A_r$$

is a decomposition into the indecomposable ideals $A_i$ of $A$. Each $A_i$ is a $K$-algebra with identity element $e_i$. By Wedderburn’s Theorem, the centers $K_i := Z(A_i)$ are finite field extensions of $K$ via $K \to K_i$, $\alpha \mapsto \alpha e_i$, and we have $K$-algebra isomorphisms $A_i \cong \text{Mat}_{n_i}(D_i)$ for each $i = 1, \ldots, r$, where $D_i$ is a division ring with $Z(D_i) \cong K_i$. The Wedderburn decomposition (9) induces decompositions

$$C = K_1 \oplus \cdots \oplus K_r$$

and

$$\mathcal{O}_C = \mathcal{O}_{K_1} \oplus \cdots \oplus \mathcal{O}_{K_r}.$$ 

Since $\mathcal{M}$ is a maximal $\mathcal{O}_K$-order of $A$, it contains the central idempotents $e_i$ and decomposes into $\mathcal{M} = \mathcal{M}_1 \oplus \cdots \oplus \mathcal{M}_r$ with $\mathcal{M}_i := \mathcal{M} e_i$. As a consequence, the ideal $f$ of $\mathcal{M}$ also decomposes into $f = f_1 \oplus \cdots \oplus f_r$ with ideals $f_i = f e_i$ of $\mathcal{M}_i$ and the ideal $g = \mathcal{O}_C \cap f$ of $\mathcal{O}_C$ decomposes similarly into ideals $g_i = g e_i$ of $\mathcal{O}_{K_i}$. In the following $p$ will usually stand for a maximal ideal of $\mathcal{O}_K$. For an $\mathcal{O}_K$-module $M$ we write $M_p$ for the completion at $p$. We let

$$J(A) := \{(a_p)_p \in \prod_p A_p^\times \mid a_p \in A_p^\times \text{ for almost all } p\}$$

denote the (“finite”) idèles of $A$ and write $U(A) = \prod_p A_p^\times$ for the subgroup of unit idèles. Here $p$ runs through all maximal ideals of $\mathcal{O}_K$. One has canonical isomorphisms

$$A_p \cong K_p \otimes_K A \cong \bigoplus_{i=1}^r K_p \otimes_K A_i \cong \bigoplus_{i=1}^r K_p \otimes_K K_i \otimes_K A_i \cong \bigoplus_{i, \mathfrak{p}} (K_i)_{\mathfrak{p}} \otimes_K A_i \cong \bigoplus_{i, \mathfrak{p}} A_i, \mathfrak{p}$$

(12)

involving various completions, where, for given $i \in \{1, \ldots, r\}$, $\mathfrak{p}$ runs through all maximal ideals of $\mathcal{O}_{K_i}$ dividing $p$ and $A_i, \mathfrak{p}$ is defined as $(A_i)_\mathfrak{p}$. More generally, for any $\mathcal{O}_{K_i}$-submodule $L_i$ of $A_i$, we denote by $L_i, \mathfrak{p}$ the $\mathfrak{p}$-adic completion of $L_i$. Using the above isomorphism, we will often write elements of $J(A)$, resp. $A_p$, as tuples $(a_i, \mathfrak{p})$, $\mathfrak{p}$, where $\mathfrak{p}$ ranges over all maximal ideals of $\mathcal{O}_{K_i}$, resp. over those that contain $p$. Similarly we denote by $J(C)$ the group of idèles of $C$. Again one has a canonical isomorphism

$$C_p \cong \bigoplus_{i, \mathfrak{p}} K_i, \mathfrak{p}$$

(13)

and we will write elements in $J(C)$, resp. $C_p$, often in the form $(a_i, \mathfrak{p})$. 

Although the torsion subgroup $DT(A)$ of $K_0(A, K)$ is its most interesting part, we need to be able to deal with the whole of $K_0(A, K) \cong \prod_p K_0(A_p, K_p)$ for most applications. In the following proposition we give the way in which we will represent $K_0(A_p, K_p)$ in the case where $A$ is a group ring. (This will do in any case where $\delta_{A_p}$ is surjective but, in general, the more varied possibilities for local projectives
will need to be taken into account.) We put $g_{i,p}$ for the $p$-part, $(g_i)_p \cap K_i$, of $g_i$ and we will use the decomposition:

\[(O_{C,p}/g_p)^\times \simeq \bigoplus_{i=1}^{r} (O_{K_i}/g_{i,p})^\times\]

**Proposition 2.7.** Let $A = \mathcal{O}_K[G]$ for some finite group $G$. For each pair $(i, \mathfrak{P})$ as in (13) we choose an element $\pi_{i,\mathfrak{P}} \in \mathcal{O}_K$, which projects to a uniformizing element in $K_i,\mathfrak{P}$ and is congruent to $1$ modulo $g_{\mathfrak{P}'}$ for each other prime $\mathfrak{P}'$ above $p$ in $K_i/K$. Then (with $\mu_p$ as in (7)) we have isomorphisms

\[K_0(A_p, K_p) \xrightarrow{\pi_{A_p}} C_p^\times / \mathfrak{n}_p(A_p^\times) \xrightarrow{\phi} I(C_p) \times \text{cok}(\mu_p),\]

where $\pi_{A_p}$ is the natural isomorphism of Theorem 2.2(ii) and $\phi$ is induced by

\[\varphi : C_p^\times \longrightarrow I(C_p) \times (O_{C,p}/g_p)^\times \]

\[\nu = (\nu_1, \ldots, \nu_r) \mapsto \left( (\prod_{\mathfrak{P} \neq p} \mathfrak{P}^{\nu_{\mathfrak{P}}} \right), (\bar{\mu}_1, \ldots, \bar{\mu}_r) \right),\]

with $\bar{\mu}_i := \nu \sum_{\mathfrak{P} \neq p} \mathfrak{P}^{-\nu_{\mathfrak{P}}}$ (using the localisation of the decomposition (11) on the left and the decomposition (14) on the right).

**Proof.** From the diagram (6), by implementing the conclusions of Theorems 2.4(iii), 2.3(i) and 2.6(ii), we have a diagram with exact rows (and canonical maps):

\[0 \longrightarrow DT(A_p) \longrightarrow K_0(A_p, K_p) \xrightarrow{\text{cok}(\mu_p)} K_0(M_p, K_p) \longrightarrow 0\]

\[0 \longrightarrow \text{cok}(\mu_p) \longrightarrow C_p^\times / \mathfrak{n}_p(A_p^\times) \xrightarrow{I} I(C_p) \longrightarrow 0\]

The rows split, since the right hand groups are torsion free, and any splitting of the map $I$ will give an isomorphism between $C_p^\times / \mathfrak{n}_p(A_p^\times)$ and $I(C_p) \times \text{cok}(\mu_p)$. Our isomorphism, $\varphi$, is given by the splitting which sends the ideal corresponding to the pair $(j, \mathfrak{P})$ to $(a_1, \ldots, a_r) \in \bigoplus_i K_i$, where $a_i = 1$ except $a_j = \pi_{i,\mathfrak{P}}$. \square

**Remark 2.8.** Since $I(C) \cong \bigotimes \mathfrak{P} I(C_p)$, isomorphisms from (15), (2) and (8) show that if $A = \mathcal{O}_K[G]$ then $K_0(A, K) \cong DT(A) \oplus I(C) \cong \text{cok}(\mu) \oplus I(C)$.

3. An Algorithm for the Computation of $K_0(A, K)$

We keep the notation of section 2 but from here until section 8, we take $K$ to be an algebraic number field and $A = \mathcal{O}_K[G]$ for some finite group $G$. In this section we present an algorithm which computes $K_0(A_p, K_p)$. By (2) it is straightforward to combine this algorithm for various $p$ to obtain $K_0(A, K)$. The algorithm presented here has been implemented in Magma, cf. [14], however only for $K = \mathbb{Q}$. We expect it to be straightforward to extend it to arbitrary $K$.

**Input:** We assume that we are given a number field $K$, its ring of integers $R := \mathcal{O}_K$ and a finite group $G$. We let $A$ denote the $R$-order $R[G]$.

3.1. Computation of $(O_{C,p}/g_p)^\times$. In [2, Sec. 3.2] it is explained how one can compute the character fields $K_i$, $i = 1, \ldots, r$, and the two-sided ideal $f$. From this the ideals $g$ of $O_C$ and $g_i$ of $O_K$, are easily deduced.

We use Algorithm 4.8.17 of [10] to compute the $p$-part $g_{i,p}$ of $g_i$ and then we can use the decomposition (14) and Algorithm 4.2.21 of [11] component-wise in order to compute $(O_{C,p}/g_p)^\times$. 
3.2. Computation of $K_1(A_p/f_p)$. The computation of $K_1(A_p/f_p)$ is completely analogous to the computation of $K_1(A/f)$ which is described in [2, Sec. 3.7]. The only difference is that we have to start with the prime ideal decomposition of $\mathfrak{p}_p$ in $[2, \text{Sec. 3.4}]$, i.e. we only consider prime ideals $\mathfrak{P}$ of $\mathcal{O}_C$ lying over the prime ideal $\mathfrak{p}$ of $O_K$.

3.3. Computation of reduced norms. The definition and computation of reduced norms is described in [3, Sec. 3.2], however, we sketch below an alternative algorithm to compute reduced norms based on the computation of reduced traces and Newton’s formulae.

We need to calculate the reduced norm $nr(M)$ of a matrix $M \in \text{Mat}_s(F[G])$, where $F$ is a field of characteristic zero. Let $E$ be an extension of $F$ containing $|G|$th roots of 1 and let $X$ be the set of irreducible characters of $G$ over $E$. (These can, of course, be calculated from the characters of $G$ over $\mathbb{C}$.) For each $\chi \in X$, let $e_{\chi}$ and $A_{\chi} = e_{\chi}E[G]$ be the idempotent and irreducible component of $E[G]$ corresponding to $\chi$. Put $d_{\chi} = \chi(1_G)$ for the degree of $\chi$. Then

$$nr(M) = \sum_{\chi \in X} nr_{A_\chi}(e_{\chi}M).$$

If we choose an $E$-isomorphism $\rho_\chi : A_\chi \cong \text{Mat}_{d_\chi}(E)$ then the reduced norm of a matrix $N = (n_{ij}) \in A_\chi$ is given by

$$nr_{A_\chi}(N) = \det(\rho_\chi(N)),$$

where $\rho_\chi(N) \in \text{Mat}_{sd_\chi}(E)$ is defined by

$$\rho_\chi(N) = (\rho_\chi(n_{ij}))_{1 \leq i, j \leq s}.$$

As in [3, Sec. 3.2], we want to calculate this without calculating a matrix representation $\rho_\chi$. We can do this by using the fact that we can easily calculate the trace of $\rho_\chi(b)$ for an element $b \in E[G]$. In fact for $g \in G$, $\chi(g) = \text{Tr}(\rho_\chi(g))$. So, extending $\chi$ linearly to $E[G]$ we obtain $\text{Tr}(\rho_\chi(c)) = \chi(c)$ for all $c \in E[G]$ and therefore

$$\text{Tr}(\rho_\chi(N)) = \sum_{i=1}^s \chi(n_{ii}),$$

or, more generally for a natural number $k$,

$$\text{Tr}(\rho_\chi(N)^k) = \sum_{i=1}^s \chi(n_{ii}^{(k)}),$$

where $\left(n_{ij}^{(k)}\right)$ is the matrix $N^k$. Of course, in (18) we have the sum of the $k$th powers of the eigenvalues of $\rho_\chi(N)$ and from these sums we can recover the elementary symmetric functions in the eigenvalues, including $\det(\rho_\chi(N))$, by recursively applying Newton’s formulae. More explicitly, let $\lambda_1, \ldots, \lambda_{sd_\chi}$ denote the eigenvalues of $\rho_\chi(N)$. We set $s_k := \sum \lambda_i^k$ and write $\sigma_k$ for the elementary symmetric functions (so $\sigma_{sd_\chi} = \prod \lambda_i$ is the reduced norm which we aim to compute). Then

$$s_k = s_{k-1}\sigma_1 + s_{k-2}\sigma_2 - \cdots + (-1)^{k-1}s_1\sigma_{k-1} + (-1)^k k\sigma_k = 0$$

for $k \leq sd_\chi$. 

3.4. Computation of cok(\(\mu_p\)). Recall the definition of \(\mu_p\) given in (7). In Subsection 3.2 we computed a set of generators of \(K_1(A_p/\mathfrak{p})\) of the form \((u)\) with \(u \in (A_p/\mathfrak{p})^\times\). Each such element we lift to an element in \(a \in A \cap A^\times\). By one of the methods of Subsection 3.3 we compute \(\text{nr}(a) \in \mathcal{O}_C \simeq \bigoplus_{i=1}^r \mathcal{O}_K\), and a representative of \(\text{nr}(a)\) by componentwise application of [11, Algorithm 4.2.24]. Using the Hermite Normal Form techniques of [11, 4.1] we compute \(\text{cok}(\mu_p)\).

This concludes the algorithm for the computation of \(DT(A_p)\).

3.5. Computation of uniformizing elements. We must choose uniformizing elements as in Proposition 2.7. For each \(i \in \{1, \ldots, r\}\) and each prime ideal \(\mathfrak{P}\) of \(\mathcal{O}_K\) lying above \(\mathfrak{p}\) we compute a uniformizing element \(\tilde{\pi}_{i,\mathfrak{P}}\) and solve the system of simultaneous congruences
\[
\begin{align*}
\pi_{i,\mathfrak{P}} &\equiv \tilde{\pi}_{i,\mathfrak{P}}(\text{mod} \ \mathfrak{P}^2), \\
\pi_{i,\mathfrak{P}} &\equiv 1(\text{mod} \ \mathcal{O}_K^{\max(1, \nu_{\mathfrak{p}}(i))}), \quad \forall \mathfrak{P} | \mathfrak{p}, \ \mathcal{O} \neq \mathfrak{P}.
\end{align*}
\]

This concludes the algorithm for the computation of \(K_0(A_p, K_p)\).

4. DISCRETE LOGARITHMS IN THE RELATIVE GROUP

From the algorithm described in Section 3 we obtain \(K_0(A_p, K_p)\) as the direct product of \(\text{cok}(\mu_p)\), which is presented as an abstract finite abelian group, and the finitely generated free abelian group \(I(C_p)\). Recall that we identified \(I(C_p)\) and \(\prod_{\mathfrak{Q} \mid \mathfrak{p}} \mathcal{P}_{i,\mathfrak{Q}}\). Hence our representation of \(K_0(A_p, K_p)\) depends on the choice of uniformizing elements \(\pi_{i,\mathfrak{Q}}\).

Let \([P, \varphi, Q] \in K_0(A, K)\). In this section we develop an algorithm which computes a representative of \([P, \varphi, Q]\) in terms of the explicit presentation produced by the algorithm of Section 3.

4.1. Outline of the algorithm. The algorithm essentially consists of the following four steps.

Step 1 Compute \(A_p\)-bases \(\nu_1, \ldots, \nu_m\) and \(\omega_1, \ldots, \omega_m\) of \(P_p\) and \(Q_p\).

Step 2 Compute the matrix \(S \in \text{GL}_m(A)\) such that
\[
(\varphi(\nu_1), \ldots, \varphi(\nu_m)) = (\omega_1, \ldots, \omega_m)S.
\]

Step 3 Compute the reduced norm \(\text{nr}(S) = (\lambda_1, \ldots, \lambda_r) \in Z(A_p)\).

Step 4 Read \(\text{nr}(S)\) in \(I(C_p) \times \text{cok}(\mu_p)\).

We briefly explain Steps 2 to 4. Step 2 is basically linear algebra and needs no further explanations. For Step 3 we can apply one of the two algorithms of Subsection 3.3 and Step 4 is completely explained by Proposition 2.7.

In the next subsection we focus on Step 1, the computation of the local bases.

4.2. Computation of a local basis. Let \(P\) be a locally free \(A\)-module and \(\mathfrak{p}\) a non-zero prime ideal of \(\mathcal{O}_K\). Let \(F = \mathcal{O}_K/\mathfrak{p}\) denote the residue class field. Then \(B := A/\mathfrak{p}A\) is a finitely generated \(F\)-algebra and \(P/\mathfrak{p}P\) is a free \(B\)-module. Let \(J = J(B)\) denote the Jacobson radical of \(B\). We set \(\bar{B} := B/J\) and \(\bar{P} := (P/\mathfrak{p}P)/J(P/\mathfrak{p}P)\). If \(\bar{\omega}_1, \ldots, \bar{\omega}_m \in \bar{P}\) is a \(\bar{B}\)-basis of \(\bar{P}\), then Nakajama’s lemma (applied twice) implies that any lift \(\omega_1, \ldots, \omega_m \in P\) of \(\bar{\omega}_1, \ldots, \bar{\omega}_m\) is an \(A_p\)-basis of \(P_p\).

Algorithms for the computation of Jacobson radicals of associative algebras over finite fields are, for example, discussed in [12, Sec. 2.3] or [13].
The algebra $\bar{B}$ is semisimple and thus isomorphic to a direct product of matrix rings $M_s(E)$, where $E$ is a finite field extension of $F$. The field $E$ and the matrix rings $M_s(E)$ can be computed by combining the algorithms in [12, Sec. 2.4 and 2.5]. The $\bar{B}$-module $\mathcal{P}$ decomposes according to the decomposition of $\bar{B}$. We are therefore left with the following problem: Given a matrix algebra $M = \text{Mat}_s(E)$ over a (finite) field $E$ and a free $M$-module $X$, compute an $M$-basis of $X$.

We let $e_{kl}$ denote the matrix $(\alpha_{ij}) \in M$ with $\alpha_{ij} = 0$ for $(i, j) \neq (k, l)$ and $\alpha_{kl} = 1$. Using basic linear algebra we compute an $E$-basis $\nu_1, \ldots, \nu_m$ of $e_{11}X$, where here $m$ is the $M$-rank of $X$. We set

$$w_k = e_{11}\nu_{(k−1)s+1} + \ldots + e_{s1}\nu_{ks}, \quad k = 1, \ldots, m.$$

**Lemma 4.1.** The elements $w_1, \ldots, w_m$ form an $M$-basis of $X$.

**Proof.** Clearly $Mw_1 + \ldots + Mw_m \subseteq X$. For the inverse inclusion we note that $X = e_{11}X \oplus \ldots \oplus e_{ss}X$. Since $e_{ij}X = e_{11}e_{11}X \subseteq e_{11}e_{11}X$ it suffices to prove $e_{11}X \subseteq Mw_1 + \ldots + Mw_m$. This is immediate from $e_{ij}w_k = e_{11}\nu_{(k−1)s+j} = \nu_{(k−1)s+j}$. $\square$

5. Discrete logarithms in the class group

In this Section we describe an approach how to solve the discrete logarithm problem in $\text{cl}(A)$ algorithmically. For that purpose we first briefly recall the main result of [2] which gives an explicit description of $\text{cl}(A)$ in terms of a certain ray class group.

We denote by $I_\mathfrak{g} = I_\mathfrak{g}(C)$ the group of fractional $\mathcal{O}_C$-ideals of $C$ that are coprime to $\mathfrak{g}$ and have

$$I_\mathfrak{g}(C) = I_\mathfrak{g},(K_1) \times \cdots \times I_\mathfrak{g},(K_r).$$

For each $i \in \{1, \ldots, r\}$ we write $\infty_i$ for the formal product over real archimedean places $\tau$: $K_i \rightarrow \mathbb{R}$ such that $A \otimes_{K_i, \tau} \mathbb{R}$ is a full matrix ring over the quaternions, and we define the ‘ray modulo $\mathfrak{g}\infty$’ by

$$P^\mathfrak{g}_\infty = P^\mathfrak{g}_\infty(C) := \{(\alpha_i\mathcal{O}_K_i) : i \in I_\mathfrak{g} \mid \alpha_i \equiv 1 \mod \mathfrak{g}, \text{ for all } i = 1, \ldots, r\}.$$

Note that $P^\mathfrak{g}_\infty$ is a subgroup of $I_\mathfrak{g}$. The main result of [2] shows that

$$\text{cl}(A) \simeq \text{cok} \left( K_1(A/f) \xrightarrow{\nu} I_\mathfrak{g}/P^\mathfrak{g}_\infty \right),$$

where $\nu$ is induced by the reduced norm.

Let $P$ be a finitely generated locally free $A$-module of rank $d$. We want to compute $(P) = \{P\} = d[A] \in \text{cl}(A)$ as an element of the right hand side in (19). We assume that we can compute an $A$-basis of $P \otimes_R K$, which in many applications is easy (compared to the problem of computing integral basis). Equivalently, we may assume that $P \subseteq A^d$.

Since we already know how to solve the discrete logarithm problem in the relative groups $K_0(A_p, K_p)$, the strategy is clear: we consider the element $\omega = [P, \text{id}, A^d] \in K_0(A, K)$. Then $\partial^\mathfrak{p}(\omega) = (P)$ and it suffices for us to solve the discrete logarithm problems for $\omega_p = [P, \text{id}, A_p^d] \in K_0(A_p, K_p)$ for each $\mathfrak{p}$. In fact, we only need to consider the finite set of prime ideals $\mathfrak{p}$ such that $\nu_p([A^d : P]_{\mathcal{O}_K}) \neq 0$, since $\omega_p = 0$ for any other prime ideal. It remains to provide, for a prime ideal $\mathfrak{p}$, an explicit description of the map

$$\partial^\mathfrak{p}_\mathfrak{p} : \text{cok}(\mu_\mathfrak{p}) \longrightarrow \text{cok} \left( K_1(A/f) \xrightarrow{\nu} I_\mathfrak{g}(C)/P^\mathfrak{g}_\infty \right),$$

where $\mu_\mathfrak{p}$ is the group of fractional ideals of $A$ with associated prime ideal $\mathfrak{p}$.
which is induced by the composite map \( K_0(\mathcal{A}_p, K_p) \subseteq K_0(\mathcal{A}, K) \xrightarrow{\partial^\circ} \text{cl}(\mathcal{A}) \). The map \( \partial^\circ \) is just the (finite) sum over the \( \partial^\circ_p \).

Let \( \omega_p \in K_0(\mathcal{A}_p, K_p) \) be represented by \( (a, \xi) \in I(C_p) \times \text{cok}(\mu_p) \). Recall that this representation depends on the choice of uniformizing elements \( \pi_i, \mathfrak{q} \) for the primes \( \mathfrak{q} \) of \( \mathcal{O}_{K_i} \) lying above \( p \). The conventions fixed in Proposition 2.7 are crucial for the validity of the following algorithm.

Let

\[
a = \prod_{i: \mathfrak{q}} \mathfrak{q}^{\xi_i}, \quad \xi = (\xi_1, \ldots, \xi_r),
\]

with elements \( \xi_i \in (\mathcal{O}_{K_i}/\mathfrak{g}_i \mathfrak{p})^\times, \ i = 1, \ldots, r. \) We choose lifts \( \eta_i \in \mathcal{O}_{K_i} \) of the elements \( \xi_i \) and consider

\[
\gamma_i := \eta_i \prod_{\mathfrak{q}} \pi_i, \mathfrak{q}^{\xi_i},
\]

where the product extends over all primes \( \mathfrak{q} \) of \( \mathcal{O}_{K_i} \) above \( p \). Let now \( \alpha_i = (\alpha_{i,q})_q \in J(K_i) \) denote the id` ele with \( \alpha_{i,q} = \gamma_i \) if \( q = \mathfrak{p} \), and \( \alpha_{i,q} = 1 \) if \( q \neq \mathfrak{p} \). It follows from the proof of [2, Th. 1.5] that the image of \( \alpha_i \) in \( I_{\mathfrak{g}_p}(K_i)/P_{\mathfrak{g}_p}^+ \) can be computed by the following recipe:

**Step 1**: Compute \( \beta \in K_i^{\times,+} \) such that

\[
v_{\mathfrak{q}}(\alpha_{\mathfrak{g}_p} \beta - 1) \geq v_{\mathfrak{q}}(\mathfrak{g}_i) \quad \text{for all } \mathfrak{q} \text{ with } \mathfrak{q} | \mathfrak{g}_i.
\]

**Step 2**: Compute the ideal \( b_i = \prod_{\mathfrak{q}} \mathfrak{q}^{v_{\mathfrak{q}}(\alpha_{\mathfrak{g}_p} \beta)}. \)

Then \( \partial^\circ_p(\omega_p) = (b_i P_{\mathfrak{g}_p}^+, i) \in \oplus_i I_{\mathfrak{g}_p}(K_i)/P_{\mathfrak{g}_p}^+(K_i) \cong I_{\mathfrak{g}_p}(C)/P_{\mathfrak{g}_p}^+(C) \), which can be computed by applying [11, Alg. 4.3.2] componentwise. Step 1 can be performed by combining the Chinese Remainder Theorem with [11, Alg. 4.2.20].

### 6. Induction, restriction and quotient map

For the moment we let \( R \) be an integral domain with quotient field \( K \). Let \( E/K \) be a field extension and \( S \) a subgroup of the finite group \( G \).

We recall that we have canonical homomorphisms

\[
\text{res}^G_S : K_0(R[G], E) \rightarrow K_0(R[S], E),
\]
\[
\text{ind}^G_S : K_0(R[S], E) \rightarrow K_0(R[G], E).
\]

If \( S \) is a normal subgroup we put \( \Sigma := G/S \). In this case we also have

\[
\text{quot}^G_{\Sigma} : K_0(R[G], E) \rightarrow K_0(R[\Sigma], E).
\]

We resume the notation of the previous sections, so \( K \) denotes a number field as before. The aim of this section is to compute \( \text{res}, \text{ind} \) and \( \text{quot} \) in terms of given explicit descriptions of the relative groups as products as in Proposition 2.7. For a fixed subgroup \( S \) we let \( C, f, g \) etc. denote the data with respect to the order \( \mathcal{O}_{K[S]} \). We write \( \text{Irr}(S) \) for the set of absolutely irreducible characters of \( S \). We fix a Galois extension \( E \) of \( K \) which is a splitting field for both \( S \) and \( G \). Then \( \text{Gal}(E/K) \) acts on \( \text{Irr}(S) \) and we write \( \text{Irr}_K(S) \) for a fixed set of orbit representatives. For \( \chi \in \text{Irr}(S) \) we let \( K_\chi \) denote the field generated over \( K \) by the values of \( \chi \). With
these notations one has
\[
\begin{array}{ccc}
K_1(K[S]) & \subseteq & K_1(E[S]) \\
\prod_{\chi \in \text{Irr}(S)} K_{\chi} & \ni & \prod_{\chi \in \text{Irr}(S)} \prod_{E} E = \prod_{\chi \in \text{Irr}(S)} E,
\end{array}
\]
where the product over \( \tau \) extends over all embeddings \( \tau : K_{\chi} \hookrightarrow E \), respectively, and the bottom map is given by
\[
(\alpha_{\chi})_{\chi \in \text{Irr}(G)} \mapsto (\tau(\alpha_{\chi}))_{\chi, \tau}.
\]
If \( G \) denotes a finite group and \( \psi \) and \( \chi \) are two (virtual) characters of \( G \), then \( \langle \psi, \chi \rangle \) denotes the standard scalar product. For a subgroup \( S \) of \( G \) and a character \( \psi \) of \( S \) we write \( \text{ind}^G_S(\psi) \) for the induced character. If \( \chi \) is a character of \( G \), then \( \text{res}^G_S(\chi) \) denotes the restriction of \( \chi \). Finally, if \( S \) is normal and \( \Sigma := G/S \), then \( \text{ind}^G_S \) is the inflated character.

6.1. Restriction. We recall that \( \text{res}^G_S : K_1(E[G]) \rightarrow K_1(E[S]) \) induces the map
\[
\begin{align*}
(\alpha_{\chi})_{\chi \in \text{Irr}(G)} & \mapsto \left( \prod_{\chi \in \text{Irr}(G)} \left( \prod_{\psi \in \text{Irr}(S)} \alpha^\psi_{\chi} \text{ind}^G_S(\psi) \right) \right)_{\psi \in \text{Irr}(S)}.
\end{align*}
\]

Let now \( \omega \in K_0(O_{K_{\gamma}}[G], K_p) \) be an element which is represented by \( (a, \xi) \in I(C_p) \times \text{cok}(\mu_p) \), as in Proposition 2.7. Recall that this representation depends on the choice of uniformizing elements \( \pi_i, \Psi \) for the primes \( \Psi \) of \( O_{K_{\gamma}} \), lying above \( p \). We want to construct \( \text{res}^G_S(\omega) \) as an element of
\[
I(C_p') \times \text{cok} \left( \mu'_p : K_1(O_{K_{\gamma}}[S]/\mathfrak{a}_p') \rightarrow (O_{C'/p}/\mathfrak{a}_p')^\times \right),
\]
where \( C', \mu'_p, f' \) and \( g' \) are chosen or defined with respect to \( O_{K[\gamma]} \), as \( C, \mu_p, f \) and \( g \) have been for \( A = O_{K[\gamma]} \). Let\]
\[
a = \prod_{i, \Psi} \Psi^e_{i, \Psi}, \quad \xi = (\xi_1, \ldots, \xi_r),
\]
with elements \( \xi_i \in (O_{K_{\gamma}/p}/\mathfrak{g}_i, \mathfrak{p})^\times, i = 1, \ldots, r \). From the explicit description of the map \( \varphi \) in Proposition 2.7 we derive the following recipe. We choose lifts \( \eta_i \in O_{K_{\gamma}} \), which are coprime to \( \Psi \) for all \( \Psi \mid p \) and consider the elements
\[
\beta_i := \eta_i a_i, \quad \text{where } a_i = \prod_{\Psi \mid p \text{ in } K_{\gamma}/K_i} \pi_{i, \Psi}^{-e_{i, \Psi}}.
\]
We now map \( (\beta_1, \ldots, \beta_r) \) to \( \prod_{\chi \in \text{Irr}(G)} E \) using (20) and call the image \( (\alpha_{\chi})_{\chi \in \text{Irr}(G)} \). Applying the map \( \text{res}^G_S \) as in (21) we obtain an element \( (\gamma_{\psi})_{\psi \in \text{Irr}(S)} \). By general theory \( (\gamma_\psi)_{\psi \in \text{Irr}(S)} \) is an element \( (\gamma_1, \ldots, \gamma_{r'}) \) of the subgroup \( \prod_{\psi \in \text{Irr}_K(S)} K_\psi \).

Again by the recipe of Proposition 2.7 we now interpret \( (\gamma_1, \ldots, \gamma_{r'}) \) as an element of \( I_p(C') \times \text{cok}(\mu'_p) \).
6.2. **Induction.** We recall that $\text{ind}^G_S : K_1(E[S]) \longrightarrow K_1(E[G])$ induces the map
\[
\text{ind}^G_S : \prod_{\psi \in \text{Irr}(S)} E^\psi \longrightarrow \prod_{\chi \in \text{Irr}(G)} E^\chi.
\]
(22)

\[
(\alpha_{\psi})_{\psi \in \text{Irr}(S)} \longmapsto \left( \prod_{\psi \in \text{Irr}(S)} \alpha^G_{\psi} \right)_{\chi \in \text{Irr}(G)}.
\]
(23)

The computation of the induction map is now completely analogous to the computation of the restriction map.

6.3. **Quotient.** In this subsection the subgroup $S$ is assumed to be normal and we let $C', f', g'$, etc., denote the data with respect to the order $O_K[\Sigma]$.

The map $\text{quot}^G_S : K_1(E[G]) \longrightarrow K_1(E[\Sigma])$ induces the map
\[
\text{quot}^G_S : \prod_{\chi \in \text{Irr}(G)} E^\chi \longrightarrow \prod_{\psi \in \text{Irr}(\Sigma)} E^\psi,
\]
(24)

\[
(\alpha_{\chi})_{\chi \in \text{Irr}(G)} \longmapsto (\alpha_{\text{inf}^G_S \psi})_{\psi \in \text{Irr}(\Sigma)}.
\]
(25)

Again, given this explicit description, the computation of the quotient map is completely analogous to the computation of the restriction map.

7. **Computational results**

In this Section we briefly recount some of the machine computations which we performed in order to check the correctness of our implementation. For more computational results the interested reader is referred to [http://www.mathematik.uni-kassel.de/~bley/pub.html](http://www.mathematik.uni-kassel.de/~bley/pub.html).

For cyclic groups $G = C_p$, $p$ a rational prime, one has $K_0(\mathbb{Z}_p[G], \mathbb{Q}_p)_{\text{tors}} \simeq C_{p-1}$. We checked this for $p \leq 23$.

Let $D_n$ denote the dihedral group of order $2n$. For odd $n$ it is known that $K_0(\mathbb{Z}[D_n], \mathbb{Q}_2)_{\text{tors}}$ is trivial. This was confirmed by our implementation for $n \leq 23$. For primes $p$ one has $K_0(\mathbb{Z}_p[D_n], \mathbb{Q}_p)_{\text{tors}} \simeq C_{p-1}$, which we also checked for $p \leq 23$.

We computed $K_0(\mathbb{Z}_p[Q_{4n}], \mathbb{Q}_p)_{\text{tors}}$ for $n \leq 25$ and $p$ dividing $4n$, where $Q_{4n}$ denotes the generalized quaternion group of order $4n$. In all cases where we have theoretical results by Theorem 1.1 our machine computations gave the correct result.

For $G = A_4$, the alternating group, we computed
\[
K_0(\mathbb{Z}_2[A_4], \mathbb{Q}_2)_{\text{tors}} \simeq C_2, \quad K_0(\mathbb{Z}_3[A_4], \mathbb{Q}_3)_{\text{tors}} \simeq C_2,
\]
obtaining the correct results (see Theorem 1.2).

We used the results of Breuning [5, Lemma 6.7 and Theorem 6.8] to test our implementations of induction and restriction.

In order to verify the correctness of the implementation of the discrete logarithm algorithm in both the relative group and the locally free class group we computed the discrete logarithm of certain Swan modules. Concretely, we computed the Swan subgroup of the locally free class group in the situations of [8, Theorems (53.13), (53.14), (53.16), (53.19)] for a list of small groups, each time obtaining the correct result.
8. Some theoretical computations

In this section, to keep the number of brackets to a minimum we write \( RG \), rather than \( R[G] \) for a group ring.

If \( A \) is an order in a semi-simple \( p \)-adic algebra \( A \), we will take the isomorphism \( \pi_A \) of Theorem 2.4(i) as an identification so that

\[
DT(A) := \mathcal{O}_C^\times/\text{nr}_A(A^\times).
\]

We denote by \( \pi, SK \) the canonical epimorphism and \( \text{nr}_A \) to \( DT(A) \). As usual we write \( SK_1(A) \) for the kernel of the reduced norm \( \text{nr}_A : K_1(A) \to C^\times \).

**Theorem 8.1.** Let \( p \) be a prime and let

\[
\begin{array}{ccc}
\mathcal{B} & \overset{\pi_3}{\longrightarrow} & A_1 \\
\downarrow \pi_2 & & \downarrow \rho_1 \\
A_2 & \overset{\pi_0}{\longrightarrow} & T
\end{array}
\]

be a cartesian square of rings (with at least one of \( \rho_1 \) and \( \rho_2 \) surjective) where \( \mathcal{B} \), \( A_1 \) and \( A_2 \) are \( \mathbb{Z}_p \)-orders in semisimple \( \mathbb{Q}_p \)-algebras \( B \), \( A_1 \) and \( A_2 \), respectively, and \( T \) is finite.

(i) Then we have an exact sequence

\[
SK_1(\mathcal{B}) \overset{\pi_3}{\longrightarrow} SK_1(A_1) \oplus SK_1(A_2) \overset{\partial}{\longrightarrow} K_1(T) \overset{\partial}{\longrightarrow} DT(\mathcal{B}) \to DT(A_1) \oplus DT(A_2) \to 0,
\]

where \( \pi_3(x) = (k_1(\pi_1)(x), k_1(\pi_2)(x)) \) and \( \rho_i(x, y) = (k_1(\rho_1)(x)/k_1(\rho_2)(y)) \).

Assume that \( B = A_1 \oplus A_2 \) (with \( \pi_1 \) and \( \pi_2 \) the projections so that \( \mathcal{B} \subseteq A_1 \oplus A_2 \)) and, for \( i = 1, 2 \), let \( \sigma_i : (\mathcal{O}_{Z(A_i)})^\times \to (\mathcal{O}_{Z(B)})^\times \) be given by \( \sigma_1(x) = (x, 1) \), \( \sigma_2(x) = (1, 1/x) \). Then

(ii) \( \partial \circ k_1(\rho_i) = \pi_3 \circ \sigma_i \circ \text{nr}_A : K_1(A_i) \to DT(\mathcal{B}) \).

**Proof.** (i) We have a commutative diagram with exact rows and columns:

\[
\begin{array}{cccc}
0 & 0 & 0 & 0 \\
\downarrow & & & \\
SK_1(\mathcal{B}) & \to & SK_1(A_1) \oplus SK_1(A_2) & \to & K_1(T) \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
K_1(\mathcal{B}) & \overset{\pi_3}{\to} & K_1(A_1) \oplus K_1(A_2) & \overset{\partial}{\to} & K_1(T) & \to & 0 \\
\downarrow \text{nr}_B & & \downarrow \text{nr}_{A_1} & & \downarrow \text{nr}_{A_2} & & \\
\mathcal{O}_{Z(\mathcal{B})}^\times & = & \mathcal{O}_{Z(A_1)}^\times \times \mathcal{O}_{Z(A_2)}^\times & \to & 0 \\
\downarrow \pi_3 & & \downarrow \pi_{a_1} & & \downarrow \pi_{a_2} & & \\
DT(\mathcal{B}) & \to & DT(A_1) \oplus DT(A_2) & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \\
0 & & 0 & & 0
\end{array}
\]

where the second row is the Mayer-Vietoris sequence for the square, c.f. [1, VII 4.3]. It is truncated at \( K_1(T) \) since the succeeding groups are torsion free by [1, IX 1.4]. This gives us our result since (by, for instance, the snake lemma) the cokernel at the top right is isomorphic to the kernel at the bottom left.

(ii) This is clear from the above diagram and follows from the explicit construction of the connecting homomorphism \( \partial \).

We note the immediate corollary:
Corollary 8.2. Let $p$ be a prime and $\Delta$ be a finite abelian group of order prime to $p$. Then $DT(\mathbb{Z}_p\Delta C_p) \cong (\mathbb{F}_p\Delta)$. \\

Proof. Consider the cartesian square:

\begin{equation}
\begin{array}{ccc}
\mathbb{Z}_p\Delta C_p & \xrightarrow{\pi_1} & \mathbb{Z}_p[\xi] \Delta \\
\downarrow \pi_2 & & \downarrow \rho_1 \\
\mathbb{Z}_p \Delta & \xrightarrow{\rho_2} & \mathbb{F}_p \Delta
\end{array}
\end{equation}

where $\xi$ is a $p$th root of 1, $\pi_1$ is induced by an isomorphism $C_p \cong \langle \xi \rangle$ and $\pi_2$ by the trivial character on $C_p$.

Since $\mathbb{Z}_p[\xi] \Delta$ and $\mathbb{Z}_p \Delta$ are commutative and semilocal, their $SK_1$'s vanish by [1, IX 1.4]. Their $DT$'s vanish because these orders are maximal. Finally $K_1(\mathbb{F}_p \Delta) = (\mathbb{F}_p \Delta)$.  

It can be quite difficult to determine the structure of $DT(\mathcal{B})$ from the sequence of Theorem 8.1(i) when both the image and the cokernel of $\partial$ are non-trivial. An easy case is the following.

Lemma 8.3. With the data and notation of Theorem 8.1, suppose that $DT(A_1) = \{1\}$ and that the canonical epimorphism $\pi_{A_2} : O_{Z(A_2)}^\times \twoheadrightarrow DT(A_2)$ is split. Then the ring extension map $\eta : DT(\mathcal{B}) \rightarrow DT(A_2)$ is split and therefore $DT(\mathcal{B}) \cong \partial(K_1(T)) \times DT(A_2)$.

Proof. We have a commutative diagram with exact second row:

\[
\begin{array}{ccc}
O_{Z(A_1)}^\times \times O_{Z(A_2)}^\times & \xrightarrow{\tau} & O_{Z(A_2)}^\times \\
\downarrow \pi_{A_2} & & \downarrow \pi_{A_2} \\
\partial(K_1(T)) & \xrightarrow{\eta} & DT(\mathcal{B}) \\
\end{array}
\]

where $\tau$ is the natural projection. Since $\tau$ and $\pi_{A_2}$ are split $\pi_{A_2} \tau$ is split and hence so is $\eta$.  

We continue our analysis of theorem Theorem 8.1 a little further to expose an easy case where the canonical epimorphism $\pi_{\mathcal{B}} : (O_{Z(\mathcal{B})})^\times \twoheadrightarrow DT(\mathcal{B})$ splits. Consider the map $\partial \circ k_1(\rho_i) : K_1(A_i) \rightarrow DT(\mathcal{B})$, for $i = 1$ or 2. Since its kernel contains $SK_1(A_i)$, it factors through $K_1(A_i)$,.

\[
\begin{array}{ccc}
K_1(A_i) & \xrightarrow{\partial \circ k_1(\rho_i)} & DT(\mathcal{B}) \\
\downarrow \text{nr} & & \\
\text{nr}(A_i^\times) & \xrightarrow{\hat{\rho}_i} & DT(\mathcal{B})
\end{array}
\]

where we have put $\hat{\rho}_i$ for the induced map.

Lemma 8.4. If $\hat{\rho}_i$ is split surjective then $\pi_{\mathcal{B}} : O_{Z(\mathcal{B})}^\times \twoheadrightarrow DT(\mathcal{B})$ splits.

Proof. (We may assume $i = 1$.) Suppose that $\gamma : DT(\mathcal{B}) \rightarrow \text{nr}(A_i^\times)$ splits $\hat{\rho}_1$. Choose $x \in DT(\mathcal{B})$ and $y \in K_1(A_1)$ such that $\text{nr}_{A_1}(y) = \gamma(x)$. Then

$\pi_{\mathcal{B}}(\sigma_1(\gamma(x))) = \pi_{\mathcal{B}}(\sigma_1(\text{nr}_{A_1}(y))) = \partial(k_1(\rho_1))(y) = \hat{\rho}_1(\text{nr}(y)) = \hat{\rho}_1(\gamma(x)) = x.$

So $\sigma_1 \circ \gamma$ splits $\pi_{\mathcal{B}}$. 

Of course, if $\rho_i$ is surjective then $DT(A_1) = \{1\} = DT(A_2)$.

The following lemma is useful in applying Theorem 8.1 when the $SK_1$’s do not vanish. What we would like is some easy-to-handle homomorphism $\nu: K_1(T) \to U$ whose kernel is the image of the $SK_1$’s...

**Lemma 8.5.** Let $A$ be an order in a semisimple $\mathbb{Q}_p$-algebra $A$ and let $\rho: A \to T$ be a ring epimorphism where $T$ is finite. Suppose that we have a group $U$ and homomorphisms $\nu$ and $\rho'$ making a commutative square:

$$
\begin{array}{ccc}
K_1(A) & \xrightarrow{\text{nr}_A} & K_1(T) \\
\downarrow k_1(\rho) & & \downarrow \rho' \\
K_1(T) & \xrightarrow{\nu} & U
\end{array}
$$

(i) We have an exact sequence

$$
0 \to \ker(\rho') \to K_1(T) \xrightarrow{(\nu)} \rho'(\text{nr}_A(A^\times)) \to 0
$$

where the first map is induced by $k_1(\rho) \circ \text{nr}_A^{-1}$ and the second by $\nu$.

(ii) So if $\ker(\rho') = \text{nr}(\ker(k_1(\rho)))$ we have an exact sequence

$$
SK_1(A) \xrightarrow{k_1(\rho)} K_1(T) \xrightarrow{\nu} \rho'(\text{nr}_A(A^\times)) \to 0.
$$

(iii) In particular, this will hold if $T$ is semisimple and the kernel of $\rho'$ is a pro-$p$-group.

**Proof.** (i) and (ii). We may complete the square to a commutative diagram with exact rows:

$$
\begin{array}{ccc}
0 & \to & \text{ker}(\rho') \\
\downarrow & & \downarrow k_1(\rho) \\
0 & \to & K_1(T) \\
\downarrow & & \downarrow \rho' \\
& & U
\end{array}
$$

$k_1(\rho)$ is surjective since $\rho$ is surjective and $A$ is semilocal ([1, IX 1.4(1)]). So $\text{img}(\nu) = \rho'(\text{nr}_A(A^\times))$ and, by the snake lemma, $\text{coker}(\rho') \cong \ker(\rho')/\text{nr}(\ker(k_1(\rho)))$.

(iii) If $T$ is semisimple, then $Z(T)$ will be a sum of finite fields of characteristic $p$. Thus $K_1(T) \cong Z(T)^\times$, and hence the middle group in the sequence of (i) will be of order prime to $p$. So the first group in the sequence, which is a $p$-group by assumption, must be trivial.

To help construct and use a suitable homomorphism $\nu$, as above, we develop further machinery based on the relationship between certain determinant maps and the corresponding reduced norms.

**Definition 8.6.** Let $A$ be a ring which is finitely generated and projective as a module over a commutative (but not necessarily central) subring $R$. We denote by $\det_R (= \det_{A,R})$ the composite

$$
\det_R: K_1(A) \to K_1(R) \to R^\times
$$
of restriction and determinant homomorphisms.
Lemma 8.7. Suppose that $R$ and $A$, as in the above definition, are $\mathbb{Z}_p$-orders in semisimple algebras $E$ and $A$, respectively (with $E \subset A$). Let $x \in K_1(A)$ with image $\bar{x}$ in $K_1(A)$. Then one has

(i) $\det_R(x) = \det_E(\bar{x})$.

(ii) $\det_R(x) = 1$ for $x \in SK_1(A)$.

Proof. (i) is clear since the ring extensions $\otimes_R E$ and $\otimes_A A$ are both given by extension of scalars functor $\otimes_{\mathbb{Z}}\mathbb{Q}$.

(ii) If $x \in SK_1(A)$, then $nr_A(\bar{x}) = 1$. Since $nr_A$ is injective this implies $\bar{x} = 1$. So $\det_R(\bar{x}) = \det_E(\bar{x}) = 1$. \qed

Let $\Gamma$ be a finite group. We recall that a $\Gamma$-Galois algebra, $L$, is a direct sum of fields on which $\Gamma$ acts by ring automorphisms, so that $\Gamma$ permutes the field summands of $L$ transitively and the stabilizer of each summand acts faithfully on that summand. The fixed ring $L^\Gamma$ is then a field (essentially a “diagonal” embedding of the fixed field of a summand) and $\dim_{L^\Gamma}(L) = |\Gamma|$. It is convenient to note that if $K$ is one of the field summands and $\Delta$ is its stabilizer then $L$ is isomorphic, as a $\Gamma$-ring, to the co-induced ring $\Map_{\Delta}(\Gamma, K)$ of $\Delta$-equivariant maps ($\Delta$ acting on the left) from $\Gamma$ to $K$ with $\Gamma$ action defined by $\gamma(f) : \gamma' \mapsto f(\gamma')$.

If the group $\Gamma$ acts on the ring $S$ by ring automorphisms and $\psi$ is a 2-cocycle in $Z^2(\Gamma, S^\times)$ then the twisted group ring (also known as a crossed product algebra) $S \rtimes_\psi \Gamma$ is the free $S$-module

$$S \rtimes_\psi \Gamma := \left\{ \sum_{\gamma \in \Gamma} r_\gamma \hat{\gamma} \mid r_\gamma \in S \right\},$$
onumber

on the symbols $\{ \hat{\gamma} : \gamma \in \Gamma \}$ with multiplication defined by the rules

$$\hat{\gamma} \hat{\delta} = \psi(\gamma, \delta) \hat{\gamma} \hat{\delta}, \quad \hat{\gamma} r = \gamma(r) \hat{\gamma}$$

for $\gamma, \delta \in \Gamma$ and $r \in S$. If the cocycle is trivial then we may omit it from the notation.

If $S$ is co-induced from a subgroup of $\Gamma$, as with a Galois algebra, then this construction produces a ring isomorphic to a matrix ring over a twisted group ring formed with the subgroup.

Lemma 8.8. Let $\Gamma$ be a finite group with subgroup $\Delta$, of index $n$. Suppose that $\Delta$ acts on a commutative ring $R$ by ring automorphisms and put $S$ for the co-induced ring $\Map_{\Delta}(\Gamma, R)$. Choose $\psi \in Z^2(\Gamma, S^\times)$. Then

$$S \rtimes_{\psi} \Gamma \cong \Mat_n(R \rtimes_{\psi} \Delta),$$

where $\psi^i \in Z^2(\Delta, R^\times)$ is defined by $\psi^i(\delta, \delta') = \psi(\delta, \delta')(1_{\Gamma})$.

Proof. Take a left transversal $T = \{\tau_1, \ldots, \tau_n\}$ of $\Delta$ in $\Gamma$. Let $e \in S$ be the characteristic function of $\Delta$ (so $e(\gamma)$ is 1 if $\gamma \in \Delta$ and 0 otherwise). Then $e_i := \tau_i(e)$ is the characteristic function of $\Delta_{\tau_i}$. Moreover, the $e_i$ are mutually orthogonal idempotents and add up to 1. Thus, putting $\Phi = S \rtimes_{\psi} \Gamma$, for brevity, we have

$$\Phi = \bigoplus_{i,j} e_i \Phi e_j = \bigoplus_{i,j} \hat{\tau}_i e \hat{\tau}_i^{-1} \Phi \hat{\tau}_j e \hat{\tau}_j^{-1} = \bigoplus_{i,j} \hat{\tau}_i e \Phi e \hat{\tau}_j^{-1} = \bigoplus_{i,j} \hat{\tau}_i \Lambda \hat{\tau}_j^{-1},$$

where $\Lambda = e \Phi e$. Now $\Mat_n(\Lambda) = \bigoplus_{i,j} \Lambda E_{i,j}$, where the $E_{i,j}$ are the (additive) elementary matrices. So we have a group isomorphism $\rho : \Mat_n(\Lambda) \rightarrow \Phi$ given by
\[ \rho(\lambda E_{i,j}) = \tilde{\tau}_i \lambda \tilde{\tau}_j^{-1}. \] Moreover, for \( \lambda, \lambda' \in \Lambda = e\Phi e, \)

\[ (\tilde{\tau}_i \lambda \tilde{\tau}_j^{-1}) (\tilde{\tau}_k \lambda' \tilde{\tau}_l^{-1}) = \begin{cases} 
\tilde{\tau}_i \lambda \tilde{\tau}_j^{-1} & \text{if } j = k \\
\tilde{\tau}_i \lambda \tilde{\tau}_j^{-1} e_\lambda \tilde{\tau}_k \lambda' \tilde{\tau}_l^{-1} = 0 & \text{otherwise,} 
\end{cases} \]

replicating the behaviour of the \( \lambda E_{i,j} \). So \( \rho \) is a ring isomorphism, also.

Now

\[ \Lambda = \bigoplus_{i, \delta \in \Delta} e_\delta \tilde{\tau}_i \bigoplus_{i, \delta \in \Delta} S\delta e_i \tilde{\tau}_i^{-1} = \bigoplus_{i, \delta \in \Delta} (S\delta)\delta = (S\delta) \times_{e_{\psi}} \Delta, \]

since, for \( \gamma, \delta \in \Delta \), we have \( e\tilde{\tau}^\gamma \delta = e\psi(\gamma, \delta)\tilde{\tau}^\gamma \delta \). Moreover, evaluation at \( 1\Gamma \) gives a \( \Delta \)-isomorphism from \( S\delta \) to \( R \). So \( \Lambda \cong R \times_{\psi'} \Delta \).

(Of course, in the situation of the lemma, the map from \( H^2(\Gamma, S^\times) \) to \( H^2(\Delta, R^\times) \) induced by \( \\
\) is an isomorphism, since \( S^\times \) is induced from \( R^\times \)).

**Corollary 8.9.** Assume the notation of Lemma 8.8.

a) \( S \times_{\psi} \Gamma \) is simple, a maximal order or hereditary if and only if \( R \times_{\psi'} \Delta \) is.

b) Let \( R = K \) be field on which \( \Delta \) acts faithfully. Then \( S \times_{\psi} \Gamma \) is simple.

c) Let \( R \) be a Dedekind domain with a quotient field \( K \) as in b). Let \( R' = R\Delta \) and suppose that \( R \) is an \( R' \)-order. Then \( S \times_{\psi} \Gamma \) is an hereditary or maximal \( R' \)-order according as \( R \) is tamely ramified or unramified over \( R' \).

**Proof.** Assertion a) is immediate from Lemma 8.8 because the properties of being simple, maximal or hereditary hold for a ring \( \Lambda \) if and only if they hold for \( \text{Mat}_n(\Lambda) \).

b) That \( K \times_{\psi'} \Delta \) is a simple algebra is a standard result (see e.g. [16, 29.6] where \( K \times_{\psi'} \Delta \) would be denoted \( (K/K^\Delta, \psi') \)). The simplicity of \( S \times_{\psi} \Gamma \) follows from part a).

In the same way we deduce part c) from [8, (28.5) and (28.7)].

**Lemma 8.10.** Suppose that \( A = L \times_{\psi} \Gamma \) is a twisted group ring where \( L \) is a finite direct sum of \( \Gamma \)-Galois algebras and \( \psi \) is a 2-cocycle of \( \Gamma \) with coefficients in \( L^\times \).

(i) For \( x \in K_1(A) \),

\[ \text{nr}_A(x) = \text{det}_L(x). \]

(ii) Suppose \( A \) is a subring of \( A \) which is projective over \( R = A \cap L \) and such that the product map \( L \otimes_R A \to A \) is bijective. Then, for \( x \in K_1(\Lambda) \),

\[ \text{nr}_A(x) = \text{det}_R(x). \]

(iii) If \( a \) is an ideal of \( R \) such that \( aA = Aa \) then we have a commutative square

\[ \begin{array}{ccc}
K_1(\Lambda) & \overset{\text{nr}_A}{\longrightarrow} & R^\times \\
\downarrow_{k_1(\rho)} & & \downarrow \sigma \\
K_1(\Lambda') & \overset{\text{det}_{\rho'}^\sigma}{\longrightarrow} & (R')^\times 
\end{array} \]

where \( R' = R/a, \Lambda' = A/aA, \rho : A \to A' \) is the reduction map and \( \sigma \) is its restriction.

(iv) If \( R \) is a \( \Gamma \)-invariant subring of \( L \) such that \( \psi \) has coefficients in \( R^\times \), \( A = R \times_{\psi} \Gamma \) and \( a \) is a \( \Gamma \)-invariant ideal of \( R \), then the conditions of (ii) and (iii) hold.
Proof. (i) We may assume that $L$ is a single Galois algebra, since the general case follows easily. So $L$ is isomorphic as a ring to $K^n$ for some field $K$ and we may assume that $L = \text{Map}_A(K, K)$ where $\Delta \subseteq \Gamma$ acts on $K$ as a Galois group.

Suppose first that $\Delta = \{1\}$. With $R = K$ and $S = L$, we adopt the notation of the proof of Lemma 8.8. Then we may identify $A$ with $K$ and $A = \Phi \cong \text{Mat}_n(K)$.

Put $e_{ij} = \tilde{e}_i \tilde{e}_j^{-1}$ (so $e_i = e_{ii}$). Then, with $f_j = \sum_i e_{ij}$, we find that $A$ is free on $f = \{f_1, \ldots, f_n\}$ over $\Gamma = \{\psi \otimes 1\} \otimes 1$.

Choose $\mu \in A^\times$ and let $\tilde{\mu} \in \text{Aut}_A(A)$ be right multiplication by $\mu$. With $\rho$ as in Lemma 8.8, let $\rho^{-1}(\mu) = M = (m_{ij}) \in \text{Mat}_n(K)$, so that $\mu = \sum_i m_{ij} E_{ij}$. Then $f_i \mu = \sum_j m_{ij} f_j$. Thus the matrix (with respect to $f$) of $\tilde{\mu} \in \text{Aut}_L(A)$ is $M$ and $\det_L(\mu) = \det(M) = \text{nr}(\mu)$.

In the general case put $F = L^\Gamma$, identified naturally with $K^\Delta$. Let $N$ be an extension of $F$ containing a copy of $K$. Then $L \otimes_F N \cong (K \otimes_F N)^{[\Gamma/\Delta]} \cong N^{[\Gamma]}$ and $(L \otimes_F N)^\Gamma \cong N$. So $L \otimes_F N$ is a $\Gamma$-Galois algebra which is “completely split” as above and we can apply the above work to $A \otimes_F N = (L \otimes_F N) \times_\Gamma \Gamma$. Thus, with $\tilde{\mu} \in \text{Aut}_A(A)$, as above,

$$\det_L(\mu) \otimes 1 = \det_{L \otimes \mathbb{Q}}(\tilde{\mu} \otimes 1) = \text{nr}_{A \otimes \mathbb{Q}}(\mu \otimes 1) = \text{nr}_{A}(\mu) \otimes 1$$

Thus $\det_L(\mu) = \text{nr}(\mu)$, as required.

Parts (ii), (iii) and (iv) are immediate. \qed

Corollary 8.11. Suppose that we have $L, A, R, A, a, R'$ and $A'$ as in Lemma 8.10(i)-(iii) and such that $L$ is finite dimensional over $\mathbb{Q}_p$, and $A'$ is finite.

(i) Then we have an exact sequence

$$0 \rightarrow \frac{\ker(\rho) \cap \text{nr}(A^\times)}{\text{nr}(\text{ker}(k_1(\rho)))} \rightarrow K_1(A') \rightarrow k_1(\rho)(\text{SK}_1(A)) \rightarrow (\text{det}_{R'}) \rightarrow 0,$$

where $(\text{det}_{R'})$ is induced by $\text{det}_{R'}$.

(ii) Suppose, further, that we have a cartesian square as in Theorem 8.1 such that $p_1 : A_1 \rightarrow T$ is $\rho : A \rightarrow A'$ as above and that

(a) $\ker(\rho) \cap \text{nr}(A^\times) = \text{nr}(\ker(k_1(\rho)))$ and

(b) $A_2$ is projective over a commutative subring $R_2$ such that $p_2(R_2) \subseteq R'$ and $A' \cong R' \otimes_{R_2} A_2$.

Then we have an exact sequence

$$0 \rightarrow \text{rho}(\text{nr}(A^\times)) \rightarrow DT(\mathbb{Q}) \rightarrow DT(A) \rightarrow DT(A_2) \rightarrow 0,$$

where, for $x \in \text{nr}(A^\times)$, $\bar{\rho}(\rho(x)) = (x, 1)\text{nr}(\mathbb{Q}^\times)$.

Proof. (i) In Lemma 8.5, take $\rho : A \rightarrow T$ to be $\rho : A \rightarrow A'$, $\nu = \text{det}_{R'}$ and $\rho' : \text{nr}(A^\times) \rightarrow (R')^\times$ to be the restriction of $\sigma$ (and hence of $\rho$). Then $\ker(\rho') = \ker(\rho) \cap \text{nr}(A^\times)$ and the result follows.

(ii) From $A' \cong R' \otimes_{R_2} A_2$ we deduce

$$\rho_2(\text{det}_{R_2}(x)) = \text{det}_{R'}(k_1(\rho_2)(x))$$

for all $x \in K_1(A_2)$. Hence $k_1(\rho_2)(\ker(\text{det}_{R_2})) \subseteq \ker(\text{det}_{R'})$. In addition, by Lemma 8.7 we have

$k_1(\rho_2)(\text{SK}_1(A_2)) \subseteq k_1(\rho_2)(\ker(\text{det}_{R_2}))$. 

We consider the exact diagram with exact rows

$$
\begin{array}{c}
0 \to SK_1(A) \xrightarrow{} K_1(A) \xrightarrow{nr_A} nr_A(A^\times) \xrightarrow{} 0 \\
0 \to \ker(\det R') \xrightarrow{} K_1(A') \xrightarrow{\det R'} (R')^\times
\end{array}
$$

By (a) we have $nr_A(\ker(\rho_1)) = \ker(\rho')$, so that

$$
\ker(\det R') = k_1(\rho)(SK_1(A)) = k_1(\rho)(SK_1(A)) + k_1(\rho_2)(SK_1(A_2)).
$$

By Theorem 8.1(i) we have

$$
0 \to K_1(A') \xrightarrow{\partial} DT(B) \xrightarrow{\partial} DT(A) \oplus DT(A_2) \xrightarrow{} 0.
$$

The exact sequence follows now since $K_1(A') / \ker(\det R') \simeq \rho(nr(A^\times))$, as is implied by the snake lemma applied to diagram (29).

Moreover if $x \in nr(A^\times)$ and $y \in K_1(A)$ such that $nr(y) = x$ then

$$
\overline{\rho}(\rho(x)) = \partial(\rho(\rho)(y)) \overset{8.1(ii)}{=} (nr(y), 1)nr(B^\times) = (x, 1)nr(B^\times),
$$

as required. □

**Remark 8.12.** By Lemma 8.5(iii), if $\ker(\rho') = \ker(\rho) \cap \ker(nr(A^\times))$ is a pro-$p$-group and $A'$ is semisimple then (a) of Corollary 8.11(ii) holds. Moreover, the semisimplicity of $A'$ implies that $\rho(nr(A^\times))$ is a finite group of order prime to $p$. Therefore the restriction $\rho' : nr(A^\times) \to \rho(nr(A^\times))$ splits. By Theorem 8.1(ii) we have the following diagram

$$
\begin{array}{c}
K_1(A) \xrightarrow{\partial(\rho)} DT(B) \\
\downarrow nr \\
nr(A^\times) \xrightarrow{\rho} \rho(nr(A^\times))
\end{array}
$$

Hence if the rest of the conditions in Corollary 8.11(ii) hold and $\overline{\rho}$ is an isomorphism then, by Lemma 8.4, $\pi_B$ splits. □

We are now in position to prove Theorem 1.2.

**Proof of Theorem 1.2** The alternating group $A_4$ is the semidirect product $V \rtimes C_3$ of the Klein group by a group of order 3 acting faithfully.

Correspondingly, $C_3$ acts on $QV \cong Q \oplus QV/(s) \cong Q \oplus Q^{(3)}$, where $s$ is the sum of the elements of $V$ and $C_3$ permutes the factors of $QV/(s)$ which is, therefore, a $C_3$-Galois algebra.

So $Q_A \cong (QV) \times C_3 \cong QC_3 \oplus ((Q^{(3)}) \times C_3) \cong QC_3 \oplus Mat_3(Q)$, by Lemma 8.8.

(i) Also $Z_4V/(S) \cong Z_4^3$. So, similarly, $Z_4A_4 \cong Z_4C_3 \oplus Mat_3(Z_4)$.

Hence $DT(Z_4A_4) \cong DT(Z_4C_3) \cong F_3^3$ by Corollary 8.2.

(ii) Pushing out the projections given by the central idempotents of $Q_2A_4$, we obtain the following cartesian square:

$$
\begin{array}{c}
Z_2A_4 \to (Z_2V/(s)) \rtimes C_3 \\
\downarrow \\
Z_2C_3 \xrightarrow{\rho_2} (Z/4)C_3.
\end{array}
$$
We put \( A_1 = (\mathbb{Z}_2 V/(s)) \rtimes C_3 \) and observe that both \( DT(\mathbb{Z}_2 C_3) \) and \( SK_1(\mathbb{Z}_2 C_3) \) are trivial, by Theorem 2.2(iv) and (v). Therefore Theorem 8.1 gives us the exact sequence:

\[
(31) \quad SK_1(A_1) \to K_1((\mathbb{Z}/4)C_3) \to DT(\mathbb{Z}_2 A_4) \to DT(A_1) \to 0.
\]

Now \( Z(A_1) = \mathbb{Z}_2 \) and the reduced norm of \((\mathbb{Q}/A_1)\) restricted to the centre is just cubing. But \( Z_2^\times \) is a 2-group and so the cubing map \( Z_2^\times \to Z_2^\times \) is an isomorphism. Thus, simply by considering elements in the centre, we can conclude that

\[
(32) \quad \text{nr}(K_1(A_1)) = Z_2^\times = \mathcal{O}_{Z(\mathbb{Q}/A_1)}^\times.
\]

So \( DT(A_1) \) is trivial.

Again, virtually the same argument shows that

\[
(33) \quad \text{nr}(\ker(k_1(\rho_1))) = \ker(\rho_1) \cap Z_2^\times.
\]

Thus, by Corollary 8.11(i) and (31), \( DT(\mathbb{Z}_2 A_4) \cong \rho_1(Z_2^\times) = (\mathbb{Z}/4)^\times \).

Lemma 8.13. Let \( R \) be a semisimple ring, \( \Gamma \) a finite group which acts on \( R \) by ring automorphisms and \( \psi \in Z^2(\Gamma, R^\times) \). Suppose that there exists an element \( u \in R \) such that \( \text{Tr}_1(u) := \sum_{\gamma \in \Gamma} \gamma(u) = 1 \). Then \( R \rtimes_{\psi} \Gamma \) is semisimple.

Proof. Let \( f : V \to W \) be an epimorphism of \( R \rtimes_{\psi} \Gamma \)-modules. We choose a \( \Gamma \)-splitting \( s^\prime : W \to V \) of \( f \). Then \( s := \sum_{\gamma \in \Gamma} \gamma u s^\prime \gamma^{-1} \) is the desired \( R \rtimes_{\psi} \Gamma \)-splitting of \( f \).

Theorem 8.14. Suppose that \( p \) is a prime, \( C_p = \langle \sigma \rangle \) is a cyclic group of order \( p \), \( \Gamma \) is a finite group, \( \overline{\Gamma} \) is a quotient of \( \Gamma \) and \( L \) is a \( p \)-adic \( \overline{\Gamma} \)-Galois algebra which is unramified over \( \mathbb{Q}_p \). Let \( \Gamma \) act on \( C_p \) so that the total action of \( \Gamma \) on \( LC_p \) is faithful. Put \( S \) for the maximal order of \( L \) and \( B = (SC_p) \rtimes_{\psi} \Gamma \), where \( \epsilon \) is a \( 2 \)-cycle in \( Z^2(\Gamma, S^\times) \). Then \( DT(B) \cong (S^p/(p))^\times \) and \( \pi_B \) splits.

Proof. Consider a Cartesian square of ring epimorphisms:

\[
\begin{array}{ccc}
SC_p \rtimes_{\epsilon} \Gamma & \xrightarrow{\pi_1} & S[\zeta] \rtimes_{\epsilon} \Gamma \\
\downarrow & & \downarrow \rho_1 \\
S \times_{\epsilon} \Gamma & \xrightarrow{\rho_2} & (S/p) \times_{\epsilon} \Gamma
\end{array}
\]

where \( S[\zeta] = S \otimes \mathbb{Z}[\zeta] \) with \( \zeta \) a \( p \)th root of 1 and \( \pi_1 \) is induced by an isomorphism \( C_p \cong \langle \zeta \rangle \). Name the rings in the square \( B, A_1, A_2 \) and \( T \) as in the square (26).

The summands of \( L[\zeta] \) are tame extensions of those of \( L \) and thus the orders \( A_1 \) and \( A_2 \) are hereditary by Corollary 8.9. Therefore \( DT(A_1) \) and \( DT(A_2) \) are trivial by Theorem 2.2(iv). In particular, \( \text{nr}(A_1^\times) = Z(A_1)^\times = (S[\zeta]/p)^\times \), so that \( \rho_1(\text{nr}(A_1^\times)) = (S^p/(p))^\times \).

Take the square (34) to be that of Corollary 8.11(ii), with \( R = S[\zeta], a = (1 - \zeta) \) and, up to an obvious isomorphism, \( R^\prime = S/(p) \). Then condition (b) is satisfied by taking \( R_2 = S \). Since \( p \) is unramified in \( S \), the ring \( R^\prime \) is a finite sum of fields and therefore semisimple. Moreover there exists \( u \in R^\prime \) such that \( \text{Tr}_1(u) = 1 \), so that by Lemma 8.13 we conclude that \( T \) is semisimple. In addition, \( \ker(\rho) \cap R^\times = 1 - (1 - \zeta)R \) is a pro-\( p \)-group so, by Remark 8.12, condition (a) of Corollary 8.11 is satisfied and the result follows by Corollary 8.11.

Theorem 8.15. Let \( G \) be the group extension \((\Delta C_p) \rtimes_{\psi} \Gamma \), where \( p \) is a prime number and
(i) $\Gamma$ and $\Delta$ are finite abelian groups of order prime to $p$.
(ii) $\Gamma$ acts by group automorphisms on $\Delta$ and $C_p$ with the action on $C_p$ being faithful and
(iii) $\psi$ is a 2-cocycle in $Z^2(\Gamma, \Delta)$.

Then

$$DT(Z_p G) \cong ((Z_p \Delta)^\Gamma / (p))^\times$$

(Note that alternative descriptions are $((\mathbb{F}_p \Delta)^\Gamma / (p))^\times$ and $\mathcal{M} / (p))^\times$, where $\mathcal{M}$ is the maximal order in $(\mathbb{Q} \Delta)^\Gamma$.)

Proof. We can represent $\mathbb{Q}_p \Delta$ as a direct sum $\bigoplus_{i,j} F_{ij}$ of $p$-adic fields where, for each $i$, $\{F_{ij}\}$ is an orbit under the action of $\Gamma$. The sum $L_i = \bigoplus_j F_{ij}$ of an orbit is then a Galois algebra for some quotient $\Gamma_i$ of $\Gamma$. Since the order of $\Delta$ is prime to $p$ the Galois algebras $L_i$ are unramified.

Now $Z_p \Delta$ is the maximal order in $\mathbb{Q}_p \Delta$ and so is the direct sum of the maximal orders $S_i$ in each $L_i$. Moreover $\psi$ splits up as the sum of 2-cocycles $\psi_i$ in $Z^2(\Gamma, S_i^\times)$. Thus

$$Z_p G = (Z_p \Delta C_p) \rtimes_\psi \Gamma = \bigoplus_i (S_i C_p) \rtimes_\psi \Gamma_i.$$

Hence, by Theorem 8.14,

$$DT(Z_p G) = \bigoplus_i DT((S_i C_p) \rtimes_\psi \Gamma_i) \cong \bigoplus_i (S_i^\Gamma / (p))^\times = ((Z_p \Delta)^\Gamma / (p))^\times,$$

as required. \qed

Taking $\Delta = \{1\}$ we have

**Corollary 8.16.** Let $G = C_p \rtimes \Gamma$, where $p$ is a prime and $\Gamma$ is a group of automorphisms of $C_p$. Then $DT(Z_p G) \cong \mathbb{F}_p^\times$. \qed

**Remark 8.17.** Let $K$ be an abelian extension of $\mathbb{Q}$ of degree $d$ and with conductor $n$ (or $\nu \infty$). Let $H(K)$ be the kernel of the natural (Artin) map $(\mathbb{Z}/n)^\times \to \text{Gal}(K/\mathbb{Q})$. If $p$ is a prime not dividing $n$ then $O_K / (p) \cong (\mathbb{F}_p)^{d/r}$, where $r$ is the order of the image of $p$ in $((\mathbb{Z}/n)^\times / H(K)$ (and hence the order of the Frobenius at $p$ in $\text{Gal}(K/\mathbb{Q}))$.

After these preparations we are finally in position to prove Theorem 1.1.

**Proof of Theorem 1.1** Let $G$ be a dihedral or quaternion group of order $2^m m$ with odd $m$ and let $p$ be a prime such that $p \mid m$ and $p^2 \nmid m$. Then

$$G = (\Delta C_p) \rtimes_\psi \Gamma,$$

with $\Delta \simeq C_{2^{n-1}m/p}$, $\Gamma \simeq C_2$ acting by inversion and $\psi \in Z^2(\Gamma, C_{2^{n-1}})$ (for details see, for example, [8, Examples (7.39), (7.40)]). So, by Theorem 8.15, we have

$$DT(Z_p [G]) \simeq (\mathcal{M} / (p))^\times,$$

where $\mathcal{M}$ denotes the maximal order in $(\mathbb{Q} \Delta)^\Gamma$. Now

$$(\mathbb{Q} \Delta)^\Gamma \simeq \bigoplus_{d\mid |\Delta|} \mathbb{Q}(\zeta_d)^+,$$

where $\mathbb{Q}(\zeta_d)^+$ denotes the maximal real subfield of the cyclotomic field $\mathbb{Q}(\zeta_d)$. Part (a) follows from Remark 8.17.
We now turn to prove part (b) and first assume that $|G| = 4m$ with odd $m$. Then $\mathbb{Z}_2 C_m$ is the maximal order in $\mathbb{Q}_2 C_m$ and is therefore isomorphic to
$$\prod_{1 \leq d | m} S_d,$$
where $S_d = \mathbb{Z}[\zeta_d] \otimes \mathbb{Z}_2$. Since $G = C_m C_2 \rtimes_\psi \Gamma$ we obtain
$$\mathbb{Z}_2 G \cong \prod_{1 \leq d | m} (S_d C_2) \rtimes_\psi \Gamma.$$

Now
$$S_1 C_2 \rtimes_\psi \Gamma \cong \begin{cases} 
\mathbb{Z}_2 V, & \text{if } G \text{ is dihedral}, \\
\mathbb{Z}_2 C_4, & \text{if } G \text{ is quaternion},
\end{cases}$$
and, therefore, in either case,
$$DT(S_1 C_2 \rtimes_\psi \Gamma) \cong C_2.$$
For $1 < d | m$ we set $A_d := S_d C_2 \rtimes_\psi \Gamma$ and $A_d := \mathbb{Q}_p \otimes_{\mathbb{Z}_p} A_d$. Then $A_d$ is a sum of $\Gamma$-Galois algebras and so, by Theorem 8.14,
$$(35) \quad DT(A_d) \cong (S_d^\Gamma / (2))^\times \cong (\mathbb{Z}[\zeta_d]^\Gamma / (2))^\times,$$
and
$$(36) \quad \pi_{A_d} : \mathcal{O}_{Z(A_d)}^\times \longrightarrow DT(A_d) \text{ splits}.$$
The result for $n = 2$ now follows from (35) combined with Remark 8.17.
Henceforth we assume $n = 3$, so that $|G| = 8m$ with odd $m$. Then with the same notation as before
$$\mathbb{Z}_2 G \cong \bigoplus_{1 \leq d | m} (S_d C_4) \rtimes_\psi \Gamma.$$
Now
$$S_1 C_4 \rtimes_\psi \Gamma \cong \begin{cases} 
\mathbb{Z}_2 Q_8, & \text{if } G \text{ is quaternion}, \\
\mathbb{Z}_2 D_8, & \text{if } G \text{ is dihedral},
\end{cases}$$
and, therefore, in either case
$$DT(S_1 C_4 \rtimes_\psi \Gamma) \cong C_2^2.$$
Suppose that $1 < d | m$. We have a cartesian square:
$$\begin{array}{ccc}
S_d C_4 \rtimes_\psi \Gamma & \longrightarrow & S_d[i] \rtimes_\psi \Gamma \\
\downarrow & & \downarrow \rho_1 \\
S_d C_2 \rtimes_\psi \Gamma & \longrightarrow & (S_d / 2) C_2 \rtimes_\psi \Gamma
\end{array}$$
where $S_d[i] = \mathbb{Z}[\zeta_d, i] \otimes \mathbb{Z}_2$.

Since $d$ is odd and greater than 1, $\mathbb{Z}[\zeta_d, i]$ is the ring of integers in $\mathbb{Q}[\zeta_d, i]$ and $\mathbb{Q}[\zeta_d, i]$ is unramified over $\mathbb{Q}[\zeta_d, i]^\Gamma$. Thus $\mathbb{Z}[\zeta_d, i] \rtimes_\psi \Gamma$ is a maximal order in $\mathbb{Q}[\zeta_d, i] \rtimes_\psi \Gamma$. Localizing, therefore, $DT(S_d[i] \rtimes_\psi \Gamma) = \{0\}$, $nr(S_d[i] \rtimes_\psi \Gamma)^\times = (S_d[i]^\Gamma)^\times$ and $nr(1 + 2S_d[i] \rtimes_\psi \Gamma) = 1 + 2(S_d[i]^\Gamma)$, since even $nr(1 + 2S_d[i]) = 1 + 2(S_d[i]^\Gamma)$. (On $\mathbb{Q}S_d[i]$, the reduced norm coincides with the algebra norm (componentwise the field norms) into $(S_d[i]^\Gamma)$. Since the extension is unramified, this norm preserves the unit filtration.)

From the last two equations it follows immediately that
$$\ker(\rho_1) \cap nr((S_d[i] \rtimes_\Gamma)^\times) = 1 + 2(S_d[i]^\Gamma) = nr(k_1(\rho_1)).$$
We set $S_d^+ := S_d^0$ and $S_d^- := \{a \in S_d \mid \gamma(a) = -a\}$, where $\Gamma = \langle \gamma \rangle$. It follows easily that
\[ \rho_1(\nu((S_d[i] \rtimes \Gamma)^\times)) = \{a + b \in \left( \frac{S_d}{2} \right) C_2 \mid a \in S_d^+, b \in S_d^-, a + bi \in S_d[i]^\times \}. \]

Since $S_d$ is unramified over $S_d^0$, it is $\Gamma$-cohomologically trivial. Therefore, there exists for each $b \in S_d^-$ an element $c \in S_d$ such that $\gamma(c) - c = b$. It follows that $b + 2c \in S_d^+$, so that indeed
\[ \rho_1(\nu((S_d[i] \rtimes \Gamma)^\times)) = ((S_d)^\Gamma/(2) C_2)^\times. \]

Therefore, from Corollary 8.11(ii), we have an exact sequence
\[ 0 \to ((S_d)^\Gamma/(2) C_2)^\times \to DT(S_dC_2) \times_\psi \Gamma \to DT((S_dC_2) \rtimes_\psi \Gamma) \to 0. \]
By (36) and Lemma 8.3 this sequence is split. Moreover, we have an exact sequence
\[ 0 \to 1 + (1 - \sigma)(S_d)^\Gamma/(2) \to ((S_d)^\Gamma/(2) C_2)^\times \to ((S_d)^\Gamma/(2))^\times \to 0, \]
where $\sigma$ generates $C_2$. This sequence also splits since the first group is an elementary abelian 2-group (of rank $\phi(d)/2$) and the third has odd order (since 2 is unramified in $S_d$). Using the result and work of the case $n = 2$, the present result now follows.

As special cases we explicitly state

**Corollary 8.18.** Let $p$ be an odd prime number and let $G$ be a quaternion or dihedral of order $2^n p$. Then $DT(\mathbb{Z}_p G)$ is isomorphic,

(i) if $n = 1$, to $\mathbb{F}_p^\times$;

(ii) if $n = 2$, to $(\mathbb{F}_p^\times)^{(2)}$;

(iii) if $n = 3$, to $(\mathbb{F}_p^\times)^{(3)}$;

(iv) if $n = 4$, to $(\mathbb{F}_p^\times)^{(5)}$ or $(\mathbb{F}_p^\times)^{(3)} \times \mathbb{F}_p^\times$, according as $p \equiv 1 \pmod{8}$ or $-1 \pmod{8}$;

(v) if $n = 5$, to $(\mathbb{F}_p^\times)^{(9)}$, $(\mathbb{F}_p^\times)^{(5)} \times (\mathbb{F}_p^\times)^{(2)}$ or $(\mathbb{F}_p^\times)^{(3)} \times \mathbb{F}_p^\times \times \mathbb{F}_p^\times$, according as, mod 16, $p \equiv \pm 1, \pm 3, \pm 5$.

**Corollary 8.19.** (i) Let $G$ be quaternion or dihedral of order 60 then

(a) $DT(\mathbb{Z}_5 G) \cong (\mathbb{F}_5^\times)^{(2)} \times (\mathbb{F}_5^\times)^{(2)}$ and (b) $DT(\mathbb{Z}_5 G) \cong (\mathbb{F}_5^\times)^{(4)}$.

(ii) Let $G$ be quaternion or dihedral of order 84 then

(a) $DT(\mathbb{Z}_3 G) \cong (\mathbb{F}_3^\times)^{(2)} \times (\mathbb{F}_3^\times)^{(2)}$ and (b) $DT(\mathbb{Z}_7 G) \cong (\mathbb{F}_7^\times)^{(4)}$.
